FOR UNLOADING HAY, GRAIN, &C.

REISSUED MARCH 3, 1863.

This Fork was awarded the First Premium, at the N. Y. State Fair, Oct. 1862, and is universally acknowledged to be the best in use. It is a Simple, Compact, and strong implement, light and easy to handle.—Will hold as much as a horse can elevate, and frequently two are employed. A boy can use it, unloading a ton of hay in five or six minutes. In view of the scarcity and high price of labor, no farmer can afford to do without it. It will save more than its cost in a season,—sometimes in a single day.

N. B.—All persons are hereby cautioned not to make, vend or use, any other Horse Fork, with tines similar to this, or which infringes upon this Patent in any respect. For Forks, address **WHEELER, MELICK & CO.**, Proprietors of the N. Y. State Agricultural Works, Manufacturers of Horse Powers, Threshers and Cleaners, Albany, N. Y. THE TRIBUNE PRIZE STRAWBERRIES.

How they Originated—How they Look and Taste—Why they are Given to the Subscribers of The Tribune—When and to Whom they will be Distributed.

The cuts herewith presented represent "THE TRIBUNE PRIZE STRAWBERRIES"—so named because we purchased them, at a very large price, to bestow *exclusively* upon the subscribers of either edition of THE TRIBUNE for 1863, intending to send one of each kind to every subscriber who expresses a wish to that effect at the time of subscribing. This will be equal to a prize of \$1.50 to each subscriber, as that is the price charged by nurserymen for similar plants. Indeed, neither of these prize strawberries could be obtained at any price whatever, as we have secured every plant that can be produced in the year 1863, exclusively, as prizes to our subscribers. We have incurred the large outlay necessary for this purpose, because we have an earnest desire to see the propagation of improved fruit greatly extended, and because we believe that every one who receives these plants and grows the fruit will hold THE TRIBUNE in kindly re-

membrance for enabling him to enjoy such a good gift of a kind Providence, and will thereafter feel an increased desire to improve all the list of fruits. It is thus that health and happiness will be increased.

As these plants have all to be grown from the few plants that we bought of Mr. Fuller in the Autumn of 1862, he will not be able to send them to subscribers until after the 1st of September, 1863, when they will be carefully packed in oiled silk or paper, and forwarded, through the mail, at our expense, or by express at expense of the receiver. The three plants will be sent to each person who sends to us a year's subscription for either the Daily, Semi-Weekly, or Weekly TRIBUNE, indicating at the time of subscribing that he desires the Strawberries, and the distribution will be made in the order the subscribers' names and requests for Strawberries are received.

Single subscribers will receive their plants by mail, done up in oiled silk, or other suitable oiled substance.

To Clubs, plants will be sent in packages, to correspond with the number of names in the Club; and where the number will warrant it, they will be sent by express, packed in boxes.

New subscribers who desire strawberry plants should say so at the time they send their money, as we do not intend to send any to those who will not appreciate them. They are too valuable to be wasted. There are parties who would gladly contract for the exclusive right to all

these plants, at 25 cents a piece, and there are many subscribers who would not, as soon as they see and taste the fruit, part with their prize for a \$5 "green back."

HOW THESE NEW STRAWBERRIES WERE PRODUCED.

The following statement is made by Andrew S. Fuller, horticulturist, Brooklyn, the originator of these strawberries. He says:

"It is now between seven and eight years since I commenced sowing seeds of the strawberry for the purpose of producing new and improved varieties. I have always selected seeds from the largest and best that could be obtained, and the results were that I produced some few good varieties each season; yet they were not such as I was willing should go out as my seedlings. Every season I selected the seed with more care than I did the previous one, and found that I made constant improvement. I therefore determined that I would put forth extra exertions and see if a few extra choice varieties could not be produced. In 1859 I obtained the best varieties known, and by fertilizing the flowers one with another, I expected to produce strawberries combining greater excellence than heretofore known. In this I was not disappointed. I produced that year many thousands of seedling plants, and the fruit of many was really excellent, so much so that I was urged not to throw the plants away; but as excellence, and not variety, was my object, I destroyed all but the most promising. I determined from the first that no plant should go out as a seedling of mine unless it combined greater excellence than any other strawberry known. From the selections of that year a competent Committee from the Farmers' Club of the American Institute, who had the matter three years in charge, made a selection of three sorts, ripening early, medium and late, and these I preserved as the final result of my seven years' laborious experiments to procure improvement in strawberries from seeds. These I intended to dispose of in the ordinary way of a nurseryman's business, and should have done so but for the desire of THE TRIBUNE to make a gratuitous distribution of these truly excellent strawberries to its subscribers. I have therefore contracted to furnish them exclusively for that purpose. Not one of them can be bought of me at any price. If I had kept them for sale to individuals the price would have been 50 cents each, or \$5 a dozen."

NAMES AND DESCRIPTIONS OF THE PRIZE STRAWBERRIES.

"The earliest ripening one was named COL. ELLSWORTH, in honor of the martyr who lost his life when Alexandria, Va., was first occupied by the Union army during the present war. It is a very large variety, of a crimson color, conical in shape, and having slight depressions running from calyx to point, resembling the sutures on the peach, with a long neck, and the calyx parts readily from the berry; quality good; flesh firm. Although the largest of the three, it is also the earliest, ripening at the same time as the Jenny Lind and Early Scarlet, and is very productive. The original plant, eighteen months from the time the seeds were sown, produced over 200 perfect berries, averaging from 1 inch to 1½ inches in diameter.

"The next ripening is called the MONITOR. It is very large, of a dark bright scarlet color, approaching a crimson in the sun. Berry very solid and firm, of fine quality; plants very vigorous and productive. This sort will become a great market fruit, the color and shape being very attractive.

"The third, from its color and origin, is called the BROOKLYN SCARLET. Although this variety is inferior in size to the other two, yet it possesses merits that will always make it a great favorite. Its shape is a regular oblong cone, color the most beautiful bright scarlet. Flavor, the very best. We have the unanimous decision of the judges at the great strawberry show last season at No. 41 Park-Road, New-York, on this point, as they awarded it the first premium over all its numerous competitors. The plant is a very strong and vigorous grower, making monstrous stools the first season, from which an enormous amount of fruit stalks are produced. Add to this its lateness, which assists so much in prolonging the season of this delicious fruit, and we have in this strawberry something as near perfection as possible, though not as large as the others. Yet this is not small, and among the sorts most cultivated, ranks medium to large."

The above descriptions by Mr. Fuller, in addition to all that we have already published, must be sufficient to satisfy all minds that we are offering no trifling prize to our subscribers, as an indication of our good will, and certainly with a hope of their continued good will to us.

We have only to add that the cuts are as exact representations as to size, as can be given, and in no respect exaggerations of THE TRIBUNE PRIZE STRAWBERRIES.

For June, July, and August Only.

A SPLENDID
Special Premium.

We know that a good Barometer is a good thing for every family. To the sailor a barometer is almost essential, and the instrument is scarcely less valuable for Farmers. It will pay a large interest on its cost every year, and very often more than pay for itself in the saving of a single crop from damage by storm. We have received many testimonials to this effect, from those who have received barometers through our premium list, and our own experience has often demonstrated the usefulness of the instrument in foreshadowing the coming storm, as well as the approach or continuance of fine weather, when

Fig. 1.

Fig. 2.

all appearances were in the contrary direction. We have hitherto given as a premium the *Aneroid Barometer*, because more portable and more readily sent by express or otherwise than the common mercurial barometer. But for the danger of breakage, we should of course prefer any good *Mercurial Barometer* as being the most nicely accurate and unfailingly permanent. This danger of breakage is now obviated in the invention of Mr. Woodruff, manufactured by Charles Wilder at Peterboro, N. H. The glass tube is well protected, and what is of great importance, and is indeed the distinguishing feature of the invention, is an arrangement by which the turning of a screw secures the mercury perfectly against motion in the tube, which has been the chief cause of breakage in transporting mercurial barometers. This new arrangement is so perfect, that with his improved mode of double boxing, the manufacturer now offers to guarantee the safe carriage of each instrument we may order, and to make good any chance loss. This guarantee places this barometer first, and we recommend it above all others for general use.

The barometers are of different forms and prices, ranging from \$5 to \$20, the price depending upon the style of finish. The tubes and working apparatus of those costing \$8 to \$20 are the same, and are supplied with inclosed thermometer, vernier, etc. Fig. 1. shows the \$8 form. Fig. 2. is the \$12 form, put in a neat or mahogany case, as desired. They are both new made, the \$12 size being of course the most ornamental, and the preferable instrument on this account.

We are glad also to announce that we have made a special advertising arrangement with Mr. Wilder (to continue only from June 1st, to August 31st.) by which these good barometers can be supplied as premiums, on terms that will place them within reach of many of our readers.

Here is our offer (the instruments to be sent direct from the manufactory by express, and their good quality and safe delivery warranted by the manufacturer, which guarantee we agree to see made good):—

1st.—The \$8 Barometer (Fig. 1) will be presented (with the guarantee as above) to any person who shall, between June 1st and August 31st, send **fourteen** subscribers to the *American Agriculturist* at \$1 a year. (The subscriptions to date January or July 1863.) See next column.

2nd.—The \$12 Barometer (Fig. 2) will be presented (with the above guarantee) to any person who shall,

between June 1st. and August 31st, send **twenty** subscribers to the *Agriculturist* at \$1 a year. (The subscriptions to date January or July 1863.

N.B. The subscribers can be sent in at any time between June 1st, and August 31st: but each name for the special premium should be specially noted as for this.

⚡ This premium is special, and applies only to subscribers received after June 1st, and before August 31st.

N.B. Any person who desires to get his barometer at once, for use during the haying season, or otherwise, can send the amount (\$14 or \$20) and receive his instrument, and then forward the names before August 31st.

⚡ The subscriptions for the above premiums may date January 1st, or July 1st, that is, at the beginning or middle of the volume. Any back numbers will be supplied.

Strawberry Premiums,
EXTRA.

Last Summer we distributed **40,000** Strawberry plants as premiums, (10 or more for each new subscriber,) sending them to all parts of the country with remarkable success. The postage on plants will be reduced one-half after July 1, and we propose to send out some more good strawberry-plants, of the very best varieties that we can obtain, as premiums to those who will during the month of **June** procure and forward subscribers to the present volume of the *Agriculturist*, at \$1 a year. The *Triomphe de Gand* will be distributed, in part, if nothing better or more desirable is found. In July, or after seeing the fruit and observing the plants this season, we will announce what kinds will be sent out. The plants will be distributed at the proper planting season, from the last of August to about October 1st; the time of sending will depend upon the season, and upon the locality to which they are to go. Those desiring the strawberry premiums will please name the fact when sending in subscribers, that their names may be put down for that purpose, and they may feel assured that they will be liberally dealt with—at least as well as in the strawberry distribution so acceptable last year.

Grape Vine Premiums.—We have about 2000 Delaware and Concord Grape Vines now planted out and growing finely, all of which we can well use on our own grounds. But as we have made it a point to raise the subscription list to the highest possible point before the middle of the volume, we still offer to send one of these vines in Autumn (safely packed, and carriage prepaid) to any one who will during this month (June) procure a new subscriber for 1863 at \$1. The vines will be sent at the proper time in Autumn, when they will have had two seasons' growth. (We have distributed 5000 vines this Spring, all of which we hope are doing well.)

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL JOURNAL, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABOR, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the *AGRICULTURIST* are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

⚡ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.

Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 224.

VOLUME XXII—No. 7.

NEW-YORK, JULY, 1863.

NEW SERIES—No. 198.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

Summer reigns. The beautiful days of June, like lovely maidens, scattered roses in the path as the advancing season journeyed from its Southern home, and now July places the regal harvest crown upon its head. Oriental splendor never equalled the gorgeousness of its court. Field and forest are waving triumphal banners, and earth refulgent with golden sunshine is a fit palace for the glorious monarch. But with the blaze of royalty comes also something of its oppressiveness. The air trembles with the waves of the sultry tide, and nature would fain seek friendly shelter from the noon-day glare. It is unwise for man to neglect the teachings of animal instinct, and while beast and bird hide themselves in the forest until the fierceness of the sunshine is abated, he too should rest from his labors. Want of time need be no excuse for imprudent exposure and exhausting labor, when, as often occurs the heat rises to above 90°. Let the labors of the harvest commence with the early dawn, be suspended during the oppressive mid-day, resumed as the sun declines, and continue while the light remains, and more can be accomplished with greater ease, and with no danger of sun stroke or exhaustion. Men should be merciful to themselves as well as to their cattle, and they will find it no less profitable.

The amount and influence of heat derived by the earth from the sun, form an interesting topic of thought for a noon-day rest, and as many cultivators will look to the *Agriculturist* for instructive entertainment on such occasions, we will note a few facts on the subject. The average amount of heat received from this source year by year, has been quite accurately determined by scientific observations. Youmans states that it has been found by careful measurement, that the quantity of solar heat which falls upon a square foot of the earth's surface in a year, would be sufficient to melt 5,400 lbs. of

ice; and as a cubic foot of ice weighs 54 lbs., the heat thus annually received, would melt a column of it 100 feet high; or in other words, if the globe were encased in ice 100 feet thick, the heat from the sun would cause it to disappear in a single year. It is true this heat is unequally distributed, for the earth moves in such a position with reference to the sun, that the rays of the latter strike less directly and consequently with less intensity upon different parts of the surface. Were this not the case, climate would be the same in all latitudes. All countries would produce the same animals and vegetables, and races of men would in time be almost wholly assimilated. But the design of the the Creator was diversity as well as harmony, and by the present arrangement we have the luxuriant vegetation, luscious fruits, mammoth animals, and fiery but unenduring men of the tropics; the useful trees, grains, and animals, and enterprising races of the temperate zones, and the stunted growth of far northern life; each fulfilling the conditions of its own sphere, and each capable of administering to the general good. It is left to the industry of man to make the stores of these different climates subservient to his own needs, and thus a constant stimulus is given to his energies. The wheat now falling before the reaper in the great West, will feed the operators in European workshops, and in return bring their wares to the door of the cultivator. Thus, though climate causes diversity, provision is made also for the brotherhood of the race, and the great law of harmony is complete. Happy will it be for the world when its working shall be developed according to the design of the Great Lawgiver.

Work for the Farm, Household, etc.

It too frequently occurs that haying and harvesting, which cannot be delayed without loss, require attention before the hoed crops have been thoroughly worked. The backwardness of the season will be likely to intensify this state of things the present year, and it should be provided against. Make thorough work in the corn field, even if it be necessary to employ extra help at high cost. Weeds left now will grow rapidly, and not only seriously diminish the yield of grain, but ripen their seed, and cause much hard work to subdue them another season. It is essential that the soil be left loose and mellow, that the roots may find their way through it easily, and that plenty of air and moisture may be supplied, which are especially needed in hot weather. A well tilled field will continue to grow during a drouth that would greatly injure corn standing on a compact, unbroken soil.

Endeavor to engage plenty of help before the busy time commences. The iron muscles of the mower and reaper are more profitable and more easily managed than human laborers. The horse pitchfork will be equivalent to one

or more extra hands. At no time of the year is more care needed to prevent loss of health by over-work, and true economy requires that whenever possible, enough help should be secured to prevent a danger from this source.

Barns and Sheds if not already in order to receive crops, should be attended to now. Have ladders or other conveniences at hand for ascending mows and stacks. Read suggestions under this head in last month's calendar. Protect such buildings with lightning-rods, and also keep them well insured against loss by fire.

Bees.—Important directions for their management are given on another page, under "Apiary."

Buckwheat.—Sow where corn has failed, and on new, or pasture land to be devoted to winter grain. A few acres with this crop may add largely to the profits of the year. The grain will be excellent ground with oats for feeding stock in the Fall, or will find a ready market when manufactured into flour. Read "Buckwheat versus Summer Fallow," on page 203.

Butter-making in hot weather requires extra care. The milk room should if possible be kept at a temperature not above 60°, by the use of ice or by cold spring water running through the room. If cellars are used for dairying purposes, keep them clean and sweet by frequent white-washing, and ventilate freely. Allow nothing having strong odor to remain in the vicinity. The barrel for sour milk, whey, etc., to be fed to swine, should never be allowed in the milk room. In sending butter to market, keep it shaded from the sun; freshly cut grass, slightly moistened, is a good material in which to pack the tubs. Keep all utensils perfectly clean and sweet, with the tinned ware scoured bright.

Cabbages may be cultivated with profit as food for stock and poultry, or for market when accessible. Transplant to ground from which early potatoes are taken this month, and sow seed now to have plenty of young plants in readiness when they are wanted for late.

Cattle for fattening next Fall should have a good start by being allowed full pasture during summer. There should be free access to water. If pasture for milch cows be short, feed night and morning with cut grass, clover, or millet, corn, etc., from the ground devoted to that purpose. Calves will thrive well upon a good growth of clover with little other feed.

Cheese is more easily managed than butter during the extreme hot season, and often more profitable. Read suggestions given on page 206.

Draining.—Observe where water stands during summer, and prepare for draining as soon as practicable. The low marshy portions of some farms contain its most valuable land, if properly reclaimed. Dry weather is best for draining if there be time and help sufficient to attend to it. Surplus capital can at any time be

profitably invested in this paying improvement.

Fences.—Keep in order, especially on farm lines, by the roadside and adjoining grain fields and meadows. A broken rail replaced may save great damage to a field of wheat, corn, or oats.

Grain.—Harvest wheat and rye just as the grain is passing well out of the milk. See page 201.

Grass and Clover Seed.—Save enough of the best growth, when it is free from weeds, for a full supply. Pull out all foreign plants, and harvest before sufficiently ripe to loose by shelling out. There is great room for improvement in grass, by selection of the earliest and best seed each successive year.

Hay.—Cut when it contains the most nourishment. Read "Hints for Haying Time" on page 202. Secure all under cover when practicable. If stacks must be made, keep them from the ground by laying upon timber and rails, and erect temporary movable roofs, or thatch with straw. Better stack grain than hay, if there be sheds for only one.

Hedge Rows, and scattered bushes may be subdued by repeated cuttings in hot weather. Allow none to disfigure the farm and give shelter to weeds, mice, and other nuisances.

Hoeing should be continued as long as practicable. Employ horse labor when possible. Cultivate lightly, in order not to destroy the roots.

Manure Making should receive constant attention. Read article on page 202.

Meadows too closely cut often receive much damage by exposure of the roots to the burning sun, especially upon light soil. A liberal top-dressing of fine barn yard manure will prevent this, and stimulate the new growth for abundant fall feed, or for a second mowing. Remove all stones and other obstructions which cause so much annoyance while gathering the crop. Keep out all stock until the grass is again strongly re-established.

Oats.—Cut as directed for wheat and rye, cure the straw thoroughly and store under cover. If properly secured, the straw is valuable for feeding.

Pastures suffer very severely if fed too closely during hot weather, so that the roots are burned by the sunshine. Keep no more stock than can be well fed, and at the same time allow the grass lands to remain in good condition. A mulching of straw upon failing spots would often be of great service; but reseeding is the only remedy where the grass has been supplanted by weeds. A crop of buckwheat will aid in subduing these, and will prepare the ground for seeding with rye in the Fall.

Poultry should be kept from the grain fields until after harvest; then they will glean enough to bring them into fine condition for laying, or for the table.

Potatoes.—Dig and market early varieties as soon as practicable, while they command good prices. The ground may then be devoted to turnips and late cabbages. Hoeing of late sorts should be finished before they blossom. High hilling is not advisable. It induces the formation of new tubers along the part of the stock covered, and prevents the growth of those already formed. It is better to plant rather deep at first, and then leave the surface nearly or quite flat. If the rot appear when the tubers are ripening, dig and dispose of them at once, that they may be used before decaying.

Seed Wheat, Rye, etc.—Read article on page 201.

Sheep.—Keep them in good condition by allowing full pasture, and providing for access to water. Give them salt weekly. Watch against foot rot.

Sorghum, Millet, or Corn may still be sown for feeding late in the season, or to be cured for fodder. This will enable many to provide against a deficiency of feed for winter.

Swine.—Keep them in a clover pasture or orchard, and feed moderately with grain until crops are harvested; then give them the range of the wheat and rye fields, where they will be well prepared for fall fattening. Give green peas with the vines, corn stalks, clover or other succulent food with milk and grain to those confined in pens. Keep their apartments well cleaned, and secure all the manure.

Tools.—See that all needed for haying and harvest are provided, and in good order. Examine mowing machines before using, and have every bolt and nut tight, the knives sharp, and all bearings well oiled. When not in use, keep all implements under cover.

Turnips.—Sow strap-leaf and other quick growing varieties among corn, after early potatoes, and on vacant ground. A dressing of good superphosphate will hasten the growth.

Weeds.—Allow none to go to seed. Those cut when nearly ripe should be burned, otherwise the seed may mature before the stalk dries, and if added to the manure heap be ready to spring up with the crops next year.

Orchard and Nursery.

Notwithstanding the bountiful crops of last year, there is a prospect that in many localities there will be plenty of fruit this year. The manure applied to the orchard in Spring is now showing its effects in a vigorous growth of wood, and in the rapidly swelling fruit. The orchard should be kept in such a condition that it will never need severe pruning, but whatever cutting is to be done should be attended to the present month. We give on another page some general hints about the pruning and treatment of the orchard.

Budding.—This will commence this month. Plums are usually the earliest stock to be worked. As soon as well formed buds can be had, and the bark of the stock parts freely, the operation may be performed. The process is fully described in the July *Agriculturist* for 1862. Though it takes some time to describe it, the operation is really a very simple one, and after a few trials it will be found that it can be done quite rapidly. Insert the bud as near the ground as possible. Use every precaution to guard against mixing or confusion of sorts. Recollect that merely budding or grafting a tree will not give good fruit unless the buds or grafts are taken from a good sort. Label distinctly at the time of budding. The stocks budded last season should be rounded off close to the new branch from the bud, and all suckers kept down.

Cherries.—In picking these for use or for market, employ only careful hands. Much damage is often done to the trees in gathering the fruit. Use a tall step ladder and draw the branches towards you with a wooden hook, easily made for the purpose.

Grafts.—Examine the grafts set this year and replace or renew the wax if it has been displaced. Vigorous shoots often start from the stock near the graft, which rob the graft of nourishment if they are not removed. Cut off all such.

Insects.—The war against these must still be carried on. Actual destruction is always a sure remedy. The tadpole-like slug which appears on the pear trees may be made to retreat by dusting with lime or ashes. These may be applied to quite tall trees by the use of a bag of some open fabric, tied to a long pole. One of our largest fruit cultivators tells us that he is troubled with no insects. His grounds are full of birds, and he is willing to give them a dessert of nice fruit after their dinner of insects. Spare the birds, and make them feel at home.

Layering.—Shrubs and vines to be propagated by this process may mostly be layered this month.

Manure and Mulch.—Bearing trees will appreciate a supply of either liquid or solid manure. During dry weather see that a good mulch is kept around trees planted this year; it retains moisture.

Thin out the fruit on trees disposed to overbear. This advice is difficult for beginners, but all experienced fruit growers know that much finer fruit is produced by thinning out freely. Dwarf trees often set fruit the first year; they should not be allowed to bear more than a single specimen or two, to test the variety, and it would be better for the tree, to take all off, and let the tree make wood only.

Weeds.—These are to be kept out of the nursery as thoroughly as from the kitchen or flower-garden. The plow, cultivator and hoe are the remedies.

Kitchen Garden.

The professional gardener does not need to be told that much of his success will depend upon the tillage given this month. But the farmer who holds field crops as of the first importance, is apt at this season to neglect the garden. Haying and harvesting engross all his attention, and the garden, begun with the best intentions, is often neglected at the very time when it needs the most care. Every odd hour should be occupied with hoeing in the garden. Much can be done here with the hoe when heavy dews prevent early morning labor in the fields, and at nightfall when the main work of the day is over. The boys should be taught to take a pride in the garden, and where there are several boys, each should have charge of a portion.

Asparagus.—Cutting should have ceased last month. The tops should be allowed to grow, and the bed will be all the better if a good coating of manure is applied. Keep down the weeds. Look out for the asparagus beetle described on page 212.

Beans.—These may still be planted for a late crop, for salting or pickling. The Refugee is considered one of the best varieties for this purpose. Limas need to be forwarded as rapidly as possible by frequent hoeings and liquid manure. When not disposed to wind upon the poles at first; twine them around carefully. When a vine reaches the height of 5 or 6 feet, pinch off the end of the main stem, and bend back all long side branches.

Beets.—Keep well hoed, and thin out to 8 or 10 inches. As the early sorts come into use, reserve the earliest and finest specimens for seed. Sowings may still be made, and if the weather is not unusually dry, a fair late crop may be expected. If necessary, transplant to fill vacancies in the rows.

Cabbages and Cauliflowers.—Finish transplanting for the late crop. If the weather is dry, extra care should be taken according to direction given last month, on page 175. Look out for caterpillars. When they are small, they remain close together, and a whole brood can be destroyed by breaking off a single leaf; if left until they become scattered, they must be removed singly. Hoe often and thoroughly, and give, to cauliflowers especially, an occasional dose of liquid manure. The early cabbages are now fit to be gathered. The stumps may be left to produce sprouts for greens, or be cleared away to make room for some other late crop.

Celery.—Plant out in well prepared trenches, shading if the weather is very hot. The growth should be forwarded by abundant watering. If the drainage is good, water may be used very freely. Keep free from weeds.

Carrots.—Hoe until the growth of tops prevents.

Corn.—The sweet varieties may be planted early this month, for late use and for drying. Plant in an extra row or two at least, to dry for the soldiers.

Cucumbers.—Plant for pickles in well prepared ground, the first of the month. Hoe those already up, and water if the weather is very dry. Recollect that there is nothing more acceptable to your friends in camp and hospital than good pickles.

Egg Plants.—These are slow growers at first. When they get well established, hurry them up by frequent hoeings and by applying manure water.

Endive.—This takes the place of lettuce as a late salad. Sow in the same way as lettuce, for late use.

Herbs.—All the aromatic herbs should be cut while they are in flower, and be either tied in small bunches or spread out thinly and dried in the shade.

Hoe.—The hoe and the rake should be kept busy whenever the ground is not too wet. If dry, hoe the oftener; cool soil condenses moisture from the air.

Insects.—The fight must still be continued according to hints given elsewhere, and in former months.

Lettuce.—In the hot Summer months, this tends to run early to seed. Sow for succession in a partially shaded place. The Silesian is one of the best varieties for Summer. Save the best heads of early sorts of lettuce, and of other plants for seed.

Manure.—Now is the time to push plants. Just before a shower and during "good growing weather," give manure in a liquid form. The home-made guano which has been saved from the poultry house will come in play now. A half bushel of this in a barrel of water, or a liquid made with cow manure, of the color of tea will do wonders in the garden. Use sink slops if you have nothing better. Apply to the roots only.

Melons.—Continue to hoe. Pinch back the vigorous growers, and if you wish choice fruit, let no more remain on the vine than can be ripened. A good part of the fruit is usually cut off by frost.

Onions.—Keep clear of weeds, and thin if the plants are crowded. See note on the maggot in last month's Calendar. Seed may be sown for small bulbs for next Spring's planting and for pickles.

Peas.—Preserve the best for seed, and pick as soon as the pods become dry. Seed may be sown for late crops, but they generally mildew. Deep planting is said to prevent this in a measure, and we have seen it stated that they will not mildew if planted at the bottom of a trench, but we have had no experience in this method of growing them. When other vegetables are abundant, late peas, though good, are not much missed late in the season.

Potatoes.—The early sorts, and none other should be grown in the garden, will be out of the way by the end of this month, and the ground may be given up to the cabbages which have been planted between the rows, or cleaned off altogether to make room for turnips, Fall spinach, etc.

Rhubarb.—The flower stalks should be cut off unless it is desirable to save seed. Tender stalks may still be pulled from near the center of the plant, but it is better to let the root recover its strength if it has been severely plucked. The stalks may be dried in the manner of apples or, what is better, may be preserved in bottles like fruit. A drink called "Rhubarb Wine" may be made from the juice according to a recipe given on page 215.

Seeds.—Early maturing seeds, such as those of cabbage and turnips, should be gathered as soon as the pods begin to turn. The stalks should be cut and the seed allowed to mature in the shade.

Squashes.—Hoe until there is danger of injuring the vines. Keep a sharp look out for insects. Hand-picking early in the morning is a sure remedy. Search for the horer described last month (on page 173). In localities where the season is short, allow each vine to bear but two or three squashes.

Tomatoes.—Pinch off the ends of the rampant branches, and remove all fruit showing signs of decay. Lay brush on the bed for the vines to trail over, or mulch with straw and let them fall down. The potato or tobacco worm, figured and described on page 108, *May Agriculturist*, often makes great havoc with the tomatoes. Search for and crush him.

Transplanting.—Vacancies in most crops can be filled by careful transplanting. Many plants are decidedly benefited by it, and few are injured if the work is carefully done. Missing hills of corn can be filled out from those containing too many plants, and other things not usually transplanted can generally be successfully moved to fill up deficiencies.

Weeds.—If there are any weeds in the garden, it is either too large, or it is neglected. You can raise weeds if you choose, but it will not be because the teachings of the *Agriculturist* have been followed.

Flower Garden and Lawn.

The backwardness of the Spring, and the dryness of the early part of June, have probably retarded many of the flowering plants, so that the present month will present a much greater variety of flowers than usual. Bedding plants may still be put out to fill the places occupied by early flowering bulbs. With skillful management, there need be no lack of attractiveness in the garden from the time frost disappears until it returns in Autumn.

Annuals.—If any of these have failed, lose no time in resowing. Though they may not mature seeds, most of them will yield a late bloom.

Bulbs.—Take up and dry as directed last month.

Carnations should now be in fine bloom. Keep the stalks tied up to stakes, and if the flower bursts irregularly, slit the calyx. Make layers and cuttings.

Climbers.—The herbaceous climbers like Ipomæas, Manrandias, Cobæa, etc., should be provided with strings or wires. Those woody ones which require to be laid down in winter, should not be allowed to interweave themselves into the lattice or trellis in a manner that will render them difficult to remove.

Dahlias.—Stakes, strings, mulch and liquid manure are the elements of success in the culture of these. Read article on training, on page 211. They may still be set with a prospect of late flowers.

Evergreens whether singly or in hedges should be pruned this month. Do not trim up the lower branches unless they are diseased. The great beauty of an evergreen consists in its broad spreading base.

Grass.—The lawn should be mowed as often as there is anything for the scythe or mowing machine to cut. If the grass is cut when very short it may be left to fertilize the lawn. Keep all edgings and the borders of lawns evenly cut. Do not allow any runners from the grass edgings to obstruct upon the borders or walks, or they will make trouble.

Keeping.—Neatness and care should characterize every department. Keep all plants which are in danger of being prostrated by winds, neatly tied to stakes, peg down bedding plants, cut away the dry flower stalks and clusters after the bloom is over, and make frequent use of the rake, to clean up.

Potted Plants that are placed about the grounds, dry out very soon and need frequent watering. They should be turned or moved occasionally to prevent the roots, which grow out through the hole in the bottom, from fastening the pot to the soil.

Rhododendrons.—These are very apt to suffer during the intense heat. Mulch their roots carefully.

Roses.—Keep pillar sorts and climbers well secured. Cut off the flower stems as soon as the bloom is past its prime. Nothing looks more slovenly than to see the ground littered with fallen rose leaves. Cut back the remontants to secure a late bloom. Treat the rose slug to a solution of 1 lb. whale oil soap in 6 gallons of water. The Aquarius will be found a convenient apparatus with which to apply it, but a common tin syringe will answer. Apply to both the under and upper side of the leaves.

Seeds.—Save the seeds of the biennials and perennials now ripening. If not needed in your own grounds they will be acceptable to friends. Label with the greatest care, and keep dry, but not hot.

Verbenas.—Keep them well pegged down. Suitable hooks for the purpose can be cut from shrubs or asparagus shoots, hair pins are sometimes used.

Water newly planted shrubs and trees if they appear to languish. Remove the surface earth, give a copious watering, and then replace the earth.

Weeds.—Use the hoe and rake frequently, and hand-weed near the plants. Begin early; the pulling of large weeds disturbs the roots of plants.

Fruit Garden.

The harvest has already begun here. A crop of nice strawberries has opened the season of fruits.

Blackberries.—Keep the canes well tied up. Where the crop of fruit is heavy the bearing branches will need support. Hoe frequently or keep well mulched.

Currants.—These often bear so heavily as to break down the branches, tie up or stake where this is the case. Gather when first ripened, for jelly. Leave those intended for bottling until fully ripe.

Dwarf Fruits.—Keep the trees planted this Spring well mulched. Summer pinching should be done. See article on page 210. Thin out the fruit from over-loaded trees. Give slugs a dusting of lime or ashes as directed above for the orchard.

Grapes.—Pinch off the bearing shoots leaving at least three or four leaves beyond the bunches. Rub off all superfluous shoots, and thus save fall pruning.

Raspberries.—These will now need daily picking. As soon as the fruiting season is over, cut down the old canes and train up the new growth; remove all superfluous shoots, leaving but two or three of the strongest to each plant. If it is desired to multiply the variety, the superfluous canes may be left to grow to be removed for transplanting in the Fall.

Strawberries.—Where the plants are cultivated in hills, keep the runners closely pinched off. If new plants are wanted, spade manure in between the rows and let the runners grow. They will soon take root and multiply with very great rapidity.

Green and Hot-Houses.

The houses are emptied of all but the tender tropical plants; those which remain need free circulation of air and frequent waterings. Where the sun is too powerful, its force should be broken by coating the glass with whitening or by a muslin screen.

Budding may now be done upon the woody plants whenever the stock is in working condition.

Callas.—Repot them now, and water less freely.

Cuttings.—A stock may be put in for plants of such varieties as are desired for winter blooming.

Earth for Potting.—Prepare a good supply and have it well mixed. The sods from an old pasture stacked up and allowed to decay, make a most excellent material; also black earth from the woods.

Grapes.—Those vines from which fruit has been gathered, should have less water and plenty of air in order that the wood may ripen. Later vines still need to be pinched in and to have the clusters thinned. Water and syringe frequently, and use sulphur if mildew appears.

Insects.—These still continue to increase and the houses will need watching. Whale oil soap and fumigation must be used from time to time.

Potting.—Seedlings should not become too much crowded. Pot before they get weak and drawn up.

Water.—Give freely and use the syringe. In very dry weather, water will be needed both morning and evening. The "aquarius" is convenient for this.

Apiary in July.

Prepared by M. Quinby—by request.

The surplus honey must be looked after this month. Do not let any of the bees lose time for want of boxes now. A good yield may be lost by putting off supplying extra boxes, for only a short time. The greatest yield of white clover is in the early part of the month, it falls somewhat toward the last, and continues a moderate show of flowers until the end of the season. The entire yield from basswood will be given in about two weeks; sometimes commencing as early as the 4th, at others as late as the 18th. Where this timber is abundant, the collections are sometimes wonderful. The flowers are pendant, and wet weather makes less difference with the honey secreted, than with clover. The honey in appearance is equal, if not superior to any other. The flavor is particularly palatable to many, on account of its peculiar aroma.... Keep a supply of boxes on hand to replace the full ones as fast as filled. One full box is preferable to two or three half filled. A little management will secure an addition to the number of full ones. A stock will often swarm too much when the boxes are only half filled, and leave too few bees to add any more. When there is no prospect of more being done, take the boxes away and give to some strong colony to finish. A box may be changed half a dozen times on some occasions, if necessary. To get rid of the bees taken off with the boxes, take an empty box, bee tight, put in the boxes on their sides, combs vertical, in such a way that the bees may creep out of all. Throw over them a sheet, that no bees may get in or out. After standing a little time, the bees, in their endeavor to escape, will get on the under side of the sheet, when it may be turned over; by repeating this a few times all may be disposed of

Bees in this way will not sting, unless provoked at first. To save the honey through the hot weather, put it in a dry place, and cool, if possible, to prevent the moth eggs from hatching. Paper or cloth may be pasted over the bottom to keep out insects. There are now more moths, than at any time before during this season, and they will be likely to find more convenient places to deposit their eggs. There will be some small swarms, some old stocks thinned by over-swarming, or queenless ones that will suffer particularly. A little assistance will save some of them from ruin. Sweep out all filth frequently, and destroy all the worms to be found. . . . Towards the last of the swarming season, preserve a few small swarms; you will find some queenless ones that will need them. But few can comprehend how soon a colony will die off, unless there is a queen present to keep up the population. A laying queen is worth much more to introduce, than a brood from which to rear one. In one case bees will be hatched in three weeks, in the other it will take six—time enough to have small colonies destroyed by the moth. When there are no available means to raise a colony strong enough to defend itself, it is best to break it up and secure the honey and wax in advance of the destruction awaiting it. Remember that as the bees get out, the worms get in—in defiance of all patent arrangements to the contrary. . . . Put some old pieces of comb under the swarms, only part full; the moth will be deceived, and lay her eggs there, when the worms are easily destroyed. Set dishes of sweetened water among the hives at night. Many insects besides the bee moth will be drowned. . . . Those using the movable comb hive, will be pleased to learn that a principle has been discovered by which all combs will be built straight. Immediately after the bees are hived, the back end of the hive is raised about 30 degrees, having the frames run from front to rear, the sides of the hive exactly vertical. When the bees have worked their combs across the top, it may be let down level. It takes but a moment to raise one end of the bottom board on blocks of wood, or bricks, and the result is satisfactory. It is believed that if these conditions are complied with, there will not be a failure. . . . All who winter bees in the open air, should be made acquainted with the importance of straw for the hives. It is probably the best available material. It is best before being threshed, and that of wheat or rye is nicest. Select it at harvest time; cut off the heads, tie in bundles, and put away until a spare time to make into hives. Make the walls of the hive two inches in thickness, and of the same proportions inside as the movable comb wood hive. At the approach of cold weather, the contents of the wood-hive—combs, honey, and bees—are transferred into straw, to pass the winter in the best condition.

The Great Strawberry Exhibition— A Monster New Seedling.

We close up the present number in the middle of the great Strawberry Exhibition, and have only room for a brief account. The previous very dry, hot weather, gave too early maturity to some varieties, while the violent driving rain on Wednesday afternoon, and rain also on Thursday morning, interfered with picking. The invasion of Pennsylvania prevented the expected large exhibition from Pittsburg and vicinity. Yet with all these drawbacks, the display was very large, and the samples very superior, showing considerable progress and improvement during the year past. It is conceded on all hands to be the finest show of the kind ever made in this country; and having ourselves seen the best displays in Europe, which were far inferior to this, we are safe in saying that the Strawberry Exhibition at the *Agriculturist* office June 18th, 19th and 20th, was the best one ever held since this delicious fruit was introduced into cultivation. The number of visitors was from 20,000 to 25,000 during the three days.

The show was a great one, not only in the amount of fine specimens presented, but especially in the size and excellence of the fruit. There were scores of plates of fruit, of such size and flavor as would hardly have been dreamed of ten years ago. On one plate were fifteen berries which, put upon the scales, weighed down a full pound avoirdupois! It takes from 120 to 150 good sam-

ples of the staple market berries of this city to weigh one pound. Triomphe de Gand berries, 22 to the pound, were also shown, and several others nearly as large. There were about 200 plates, usually containing one to two quarts each, shown by 26 exhibitors. Omitting notice of many other excellent and improved seedlings until our next number, we will only add, that one of the great centres of attraction was the new, unnamed seedling (No. 10) shown by Mr. Seth Boyden, of Newark, N. J., the well known inventor of the processes of making Malleable Iron, patent leather, etc. It is a product of Peabody's Seedling with the Green Prolific, the latter produced from Kitley's Goliath and Hovey's Seedling. It has therefore a most excellent pedigree. Its form is nearly conical, somewhat necked; deep scarlet color, extending to the core; solid, and of pleasant pine flavor. The size is enormous, the average berries exceeding anything ever before seen in the strawberry line. Both the plant and berry will be described and illustrated hereafter. To save useless letters of inquiry to Mr. Boyden (or ourselves), we will state, that no speculation will be allowed with this new and remarkable strawberry—no "\$5 a dozen when ten thousand purchasers are secured." Not a single plant is for sale on any terms, but it will be multiplied as rapidly as possible, and next year the plants that can be produced in the meantime, will be given away as a donation to the public. Previous to the announcement of the time and manner of distribution, no applications for plants will be answered by Mr. Boyden or others.

PRIZES AWARDED.

- Best 25 varieties, one quart each, \$7, to Wm. F. Heins, Morrisania, N. Y.
 Second do., \$5, A. S. Fuller, Brooklyn, N. Y.
 Best Dish Market Berries (2 qts), \$3, to L. M. Pease, N. Y. Farm School, Mt. Vernon, for Triomphe de Gand.
 Second do., \$2, to S. R. Trembley, Bergen Point, N. J., for Union variety.
 Third do., \$1, to L. M. Pease, for Wilson's Albany.
 Largest Berries (weight and size considered), \$2, to Seth Boyden, Newark, N. J., for the New Seedling.
 Best New Seedling, not before exhibited, \$5, to Seth Boyden, Newark, N. J., for his unnamed, No. 10, the New Seedling.
 Second do., \$2, to J. W. Faulkner, Stamford, Ct.
 Best flavored Strawberry, (1 quart), \$2, to A. S. Fuller, Brooklyn, unnamed Seedling No. 8.
 Best Quart White Strawberries, \$2, to Jno. Drummond, Gardener to Mrs. Jas. Strong, Newtown, L. I., Bieton Pine.
 Best Pint of Empress Eugenie, \$1, to E. Marshall, Poughkeepsie, N. Y.
 Best Quart Fillmore, \$1, to E. Williams, Mt. Clair, N. J.
 Best Quart of Cutter's Seedling, \$1, to E. Marshall, Poughkeepsie.
 Best Quart of Triomphe de Gand, \$1, to F. W. Devoe, Fordham, N. Y.
 Best Quart Wilson's Albany, \$1, to L. M. Pease, Mt. Vernon, N. Y.
 Best Quart of Hooker's Seedling, \$1, to Francis Brill, Newark, N. J.
 Best Quart Hovey's Seedling, \$1, to E. Williams, Mt. Clair, N. J.
 Best Quart of Jenny Lind, \$1 to John Drummond, Gardener to Mrs. Strong, Newtown, L. I.
 Best Quart Vicomtesse Hericart deThury, \$1, to H. C. Fuller, Godwinville, N. J.

Great American Exhibition of Pumpkins, Squashes, and Ornamental Gourds.

The Second Annual Exhibition of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS, at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 4th, 1863, at which the following Prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS,

- A—For the Heaviest Pumpkin or Squash.....\$10.00
 B—For the 2nd Heaviest Pumpkin or Squash... 5.00
 C—For the 3rd Heaviest Pumpkin or Squash.... 3.00
 D—For the Best Pumpkin or Squash for cooking. 5.00
 E—For 2nd Best Pumpkin or Squash for cooking. 3.00
 F—For the largest yield on a single Vine.....10.00
 G—For the 2nd largest yield on a single Vine... 5.00
 H—For the largest and finest collection of Fancy or Ornamental Gourds..... 7.00
 I—For the 2nd largest and finest collection of Fancy or Ornamental Gourds..... 4.00

*All to be grown by one person and to be accompanied by positive evidence from the grower, and one disinterested person who assists in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 15th, and deliver specimens for competition on or before Nov. 2d. Specimens to be delivered free of charge.

Note 3.—The same specimen can compete for only one of the premiums offered above.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

Editor Absent.—The June and July numbers of the *Agriculturist* are issued without the direct assistance and supervision of Mr. Judd, who is making his usual Summer tour to observe and study the general farming operations of the country. This year he will happen, often unawares, or *incognito*, among some of our readers at the West, especially in the Prairie States.—We trust the "matter and manner" of these two numbers will, in part at least, show a realization of the Proprietor's idea, viz.: to have a sufficient force to carry on the journal in full vigor, even should sickness or death, or other causes chance to deprive it of one or more of its leading editors. The *Agriculturist* has come to be an "institution" not dependent upon the life or efforts of any single man.—Personal letters, may for the time being, remain unanswered. All business matters connected with the paper will be promptly attended to. We hope to exhibit to the Proprietor on his return, a large increase in the subscription lists. The premiums offered are worth working for.

ASSOCIATE EDITORS.

The Premiums Close July 31.

That there may be no disappointment, we repeat that all premiums of every kind, general and special, will close on July 31, excepting only the new Barometer Premium, and the Wringing Machine No. 2; these will continue open to August 31. For special Premiums see page 224. For general Premiums see page 155, June No. It is not probable that we shall offer any premiums in future.

The Strawberry and Grape Pre-

miums are continued this month, and now is the only time to secure them. See page 224. A clergyman, in Illinois, writes us that the 25 plants received last year for two subscribers, multiplied so that he gave away several lots of 50 plants to his friends, and had more to give away in the same manner, besides a plot as large as he wanted for fruit for his own family. From what we hear, we judge there are millions of improved strawberry plants growing in the country, which sprung from the forty thousand plants sent from the *Agriculturist* Office last year.

Criticisers of Advertisements will please read last article on page 163 of June *Agriculturist*. They need not read the Tribune and Herald advertisements last month and this.

Farm House Plans.—E. T. Benedict, Cuyahoga Co., O. We hope ere long to give plans for a commodious and economical farm dwelling; meantime we invite subscribers to forward designs for such buildings, suitable for the accommodation of a family of eight or ten persons, the cost not to exceed two thousand dollars, and, as much less as practicable. Especial attention should be given to make the rooms convenient for doing the housework.

Sorgho Mills and Boilers.—To several inquirers. We can not answer all the questions sent in. The "Clark Sorgho Machine Company" of Cincinnati, make good Mills, and Blymyers, Bates & Day, of Mansfield, O., make the Cook's Evaporator, which, from all accounts, seems to be the favorite boiler. The advertisements of both these parties may be found on another page, and by addressing them, much of the information required can be readily obtained.

Good Hemp Brake.—E. D. Gaines, Grant Co., Ky. The newly invented brake of Mallory & Sanford, advertised in this number, breaks hemp even more perfectly than flax. The fibre comes out entirely free from woody matter, and without any waste from tow. It can be worked by any ordinary horse power machine.

Barren Grape Vines.—C. J. Hollingsworth, Herkimer Co., N. Y. If the fruit sets on the vine after blossoming and fails to come to perfection, the difficulty may be in improper location, poor soil, or want of proper pruning. If, however, the blossoms do not develop into fruit, it is undoubtedly owing to a radical defect in the blossoms themselves, probably to the absence of stamens with which to fertilize the pistils. Such plants, called pistillates, are quite common. Several kinds of strawberries have only one set of organs. The only way to secure fruit from such, is to supply them with pollen from other plants having the reproducing organs complete. It is usually done by planting staminate varieties near the barren sorts; the pollen is carried to the plant lacking it, by the wind and by insects.

Value of Goats.—"A subscriber to the *Agriculturist* asks about the value of goats kept for milk, with information as to their desirableness, etc. They have some excellent qualities, but some that are particularly undesirable. They may be kept very cheaply, as they will eat almost any green thing, and many weeds which other animals refuse. We have seen a goat eagerly feeding on brown paper. Their milk is very rich, and considered excellent food for children. But they are also very mischievous if allowed to run at large. Not a flower, plant, or tree is safe from their depredations. If kept at all, it should be in an enclosure where they can do no harm. Then if the pasture be rich, a good goat will probably yield milk enough to be profitable.

Scab in Sheep.—O. L. Walter, Luzerne Co., Pa. This disease is caused by the presence of a minute parasitic insect, which burrows in the skin of the sheep. It is very contagious. Infected animals should be separated from the flock, the scabs scoured off with a stiff brush and soap suds, and afterward dipped in a strong decoction of tobacco mixed with a little spirits turpentine.

To Destroy Sheep Ticks.—John Scott, Niagara Co., N. Y. Immediately after shearing, dip the sheep and lambs in a pretty strong decoction of tobacco. This will destroy the ticks without injuring the flock.

Insuring Sheep against Dogs.—Geo. I. Evans, Jefferson Co., Ohio, writes that since the Legislature of that State refuses to tax dogs, the Trenton Farmer's Club proposes to organize itself into a sort of Insurance Co. for protection of sheep. We suppose it would only extend to members of the club who would be assessed to pay for the sheep destroyed each year.

Proof against Sheep-Killing Dogs.—C. H. Field, Westchester Co., N. Y., writes to the *Agriculturist* that conclusive proof against sheep-killing dogs may often be had, by examining their mouths. Small pieces of wool will be found between their teeth for several days after they have been on a foray. They are cunning enough to wash off marks of blood, but can not pick their teeth so readily.

Ringbone in Horses.—C. D. Wilson, Chautauqua Co., N. Y. This disease is often hereditary. Colts but a few months old have frequently been affected with it. It may be caused by any strain of the ligaments in the region of the pastern joint. There is no complete cure known. Lameness may be removed by rest, and stimulating liniments, or counter irritants, as blistering the skin. Prevention is found in careful usage.

Cure for Scratches.—"Non Equus" contributes to the *Agriculturist* the following remedy for scratches in horses, which he says is infallible: Mix one ounce of verdigris (sub-acetate of copper) with a gill of unsalted lard, and daily anoint the affected parts with a teaspoonful of the ointment. The feet and legs of the animal should be washed with warm soap suds, and wiped dry, before applying this preparation.

Warts on Horses.—Samuel Thompson, Salem Co., N. J., writes to the *Agriculturist* that he has been successful in removing warts from horses without resorting to the knife. He uses a mixture of one part flowers of sulphur to two parts of Alcohol by measure, to be well shaken and applied daily until the wart disappears.

To Keep Rats from Harness.—Samuel Thompson, Salem Co., N. J., recommends to mix a little tar with the oil used on harness, which he says will keep rats from gnawing it.

Gapes in Chickens.—"Inquirer." Prevention is better than cure. Young chickens kept in dry, clean quarters, and fed with cracked corn, the size of the pieces being suited to their age, are seldom affected with this ailment. Many remedies have been published; the favorite one is to dip the feather end of a quill in spirits turpentine, open the mouth of the chicken and twist the feather in its windpipe. This will remove or destroy the small worms which accompany the disease, and sometimes effect a cure.

A Mischievous Bird.—Noah B. Aiken, Lorain Co., O., writes to the *Agriculturist*, that the Barn Wren is a very troublesome bird, throwing out the eggs from the nests of swallows and other birds, and thereby meriting shooting at sight. We are not acquainted with any bird of such habits. It certainly cannot be the common wren, which though resolute in defending its own premises, is not, to our knowledge, an invader of the

rights of others. Can any one give such a description as shall certainly designate this mischievous bird, and give a warrant for its execution?

Sparred Floors for Cattle.—"Farmer." Erie Co., N. Y. We somewhat question the expediency of using them, especially in Winter. The liquid manure will indeed pass away readily, but then the cold winds will also blow up through them, making the stalls chilly and unwholesome. Manure will freeze worse in such stalls than in others. And moreover, a grating makes an unpleasant footing for man or beast.

Red Durham Cattle.—L. W. Goodrich, Piscataquis Co., Me. Certainly, there are imported Durhams whose color is uniformly red, and whose blood is as pure as the white or roan stock.

Protecting Bee-Hives from Ants.—J. Hills, writes to the *Agriculturist* that he effectually protected his hives from black ants, which had previously been very troublesome, by placing the supports of the stand in troughs of water. The insects were unable to swim over, and the hives were left unmolested.

Mignonette for Bees.—Walter Fish, an Apiarian of Clackamas Co., Oregon, seeing it recommended to sow mignonette for bees to make honey of, tried the experiment and found the honey made from the blossoms had a strong odor like that of buckwheat. Mignonette is an annual, worthless, as he says, save for honey, while buckwheat blooms all Summer and then gives a crop of grain. He says white clover is better than either for honey, good for stock, and fine to turn under as a fertilizer.

Non Swarming Hives.—In reply to a communication to the *Agriculturist* on the value of non-swarming hives, by Jasper Hagen, Mr. Quinby writes: "J. H. presumes because he has had some experience with a half dozen hives, two or three years, in one place, that all other bees in the country will do the same. These non-swarming hives, are not to be depended upon as such. Until we can get one that will, it seems like a waste of time to discuss their profit as compared with the swarmer. I have had no reason to change the opinion given ten years ago on this point, in the 'Mysteries of Bee-Keeping,' pages 37-8 and I have had much subsequent experience on this point. In this locality, I find three in eight will swarm, even when put in the dark room.... In such room, the surplus honey is in bad shape for market. A good non-swarmers is a very desirable article, and one that would give the surplus honey in good shape for market, and could be reliable at all times, or only nine in ten, would, to me at least, be worth hundreds of dollars."

Bottling Insects.—During an insect discussion at the New-York Fruit Growers Meeting, Dr. Trimble protested against the method of wholesale destruction practised by some persons who hang open bottles of sweetened water in fruit trees to entrap insects. His argument was, that "in so doing one destroyed more friends than enemies; we should rather encourage the increase of the clear-winged fly, the lady bug, etc., as these prey upon destructive insects."

Trap for Wire Worms.—A correspondent of the London Gardeners' Chronicle was successful in ridding a grape vine border of wire worms by the following plan: Potatoes were cut in slices half an inch thick, and inserted at short intervals along the border, about two inches below the surface. A small stick was placed to show the locality of each place. The potatoes were regularly inspected every morning for about three weeks, and large numbers of worms were daily found in them. In this way the ground was ultimately cleaned of these destructive pests.

Scale on Apple Trees.—"G." of St. Paul, Minn., referring to the bark-louse question in the June *Agriculturist*, says he had a tree growing on poor soil which was completely covered with scale. He made a strong lye from wood ashes, and applied it with a stiff wisp broom. The first rain washed it clear of scale, the leaves came out healthy, and it bore its first crop of fruit that year. He has since used lye with like good success, without injuring the trees.

Bean Weevil.—C. R. Thomas, Warwick Co., Ind., and others. We have had no experience with this insect, but suppose that it may be destroyed like the pea-bug, by scalding the seed before planting.

Potato Bug.—S. J. Noble, Dorchester Co., Md., says that the most effectual way to destroy the potato bug "is to take a tin bucket or basin in one hand,

and the potato top in the other; shake the bugs into the bucket or basin and you have got them to burn or bury at your pleasure. I have captured gallons of them in this way." We do not know to which particular bug Mr. N. refers, but his advice is sensible as regards any of the many species which infest the potato. The only way in which we can get rid of insects, aside from the help of birds and parasites, is actual destruction. There are no specifics or particular remedies for each insect. We must study their habits and work for their destruction in the stages of egg, larva, and perfect insect. By destroying the moth, butterfly, or beetle, we prevent their multiplication, but as these are the forms in which insects appear to be most harmless, we mainly direct our efforts toward the larva. Destroy the perfect insect, and the destructive larva will cease.

The Chess Question.—D. Noble, Shawanaw Co., Wis., thinks that we do wrong to decline discussion on this subject. We might fill our pages with arguments on either side of this or any other public fallacy. We are willing to admit even, that the moon is made of green cheese, if we can see an authentic specimen. If he has an example of the transmutation of one grain into another we will not even decide on it ourselves, but submit it to the first botanists of the country, and if they say that the specimen is partly wheat, or any other grain, and partly chess we will give it up. Send the specimens.

Sweet Potato Tops for Fodder.—K. Horner, Wayne Co., Mich., asks if sweet potato tops are suitable food for animals. He has had good success in raising the crop in his locality and finds that cows and hogs are fond of the tops. We have always let the tops remain until the frost killed them, and have had no experience in feeding. The sweet potato belongs to the same family as the jalap, and we should expect to find some cathartic property in the uncooked plants. Mr. H's experience is, that the cattle and hogs eat them without injury. We shall be glad to hear from others who have tried the experiment. Where the potatoes are dug before frost it may be desirable to feed out the tops, if it can be done with safety.

Pond Mud.—James Floyd, Chenango Co., N. Y., wishes to know, whether the cleanings of the canal every spring, will answer for a top-dressing of his meadow? We have often noticed such heaps on the canal bank, covered in Summer with a rank growth of Canada thistles, dock, etc. The best way to manage such mud is to cart it home, spread it in layers from four to six inches thick, and cover each layer with a coat of lime. Let the heap lie a few months, and then shovel it all together. After laying a short time longer, it may be spread on meadows, pastures or anywhere. The lime will kill most of the foul seeds, and decompose the vegetable and animal matter in the mud.

How to make a Manure Heap.—Wm. Polly, Dark Co., O., writes to the *Agriculturist* that he has an old straw heap, trodden by cattle last Winter, a few loads of manure from the horse stable, a few ashes, and that he can obtain plenty of lime. He has also a good shed under which to make the heap, and asks how to proceed. Place a layer of straw a foot thick, then two inches of ashes or lime, next two inches of manure, or rich soil. Add six inches of horse manure, more straw and ashes or lime, then earth and manure as before, and when the pile is complete, cover the whole with two or three inches of manure or earth. Water the heap moderately and every two weeks fork the whole over, until the ingredients are thoroughly mixed. In the mean time add to the pile all the house slops, the contents of the pig-pen and privy. In two months or less there will be a valuable compost heap ready for use next Fall.

Disinfectants.—E. H. Morton, Middlesex Co., N. J. To deodorize offensive substances, such as the contents of privies, sink drains, &c., so as to use the materials afterward for compost, is an important matter. When powdered charcoal is abundant, nothing is better, putting it in layer after layer. But when this is scarce, dried peat or muck will answer nearly as well. If, however, the decaying substances still emit offensive odors, powdered lime may be added. In ordinary cases, coal ashes, tan-bark, saw-dust, or dry soil will absorb refuse liquids and turn them into useful fertilizers. It is essential that the absorbent be well dried.

Out Door Whitewash.—E. J. Hammond, Harford Co., Md. We know no better recipe for preparing whitewash for fences and other wood work exposed to the weather, than the following, which was published in the *Agriculturist* several years since. Mix unslacked lime with about as much water as will be required in use, and add about half a pound of tallow for

each neck of lime. As the lime slakes, the heat will melt the tallow, which is to be thoroughly stirred, the stirring to be repeated while using, if any of the grease rises to the surface. Spoiled lard or other grease may be used in place of tallow.

Sowing Grass with Buckwheat.—

A. L. Fowler, Litchfield Co., Conn. It would not be advisable to sow grass seed with buckwheat. The latter would shade the ground too much for the grass to get a good start. Better sow with buckwheat alone, and seed down with rye next Fall. Or, if it be desirable to start the grass at once, try a crop of millet, sowing it rather thinly; this will give the grass as good chance as winter grain, or oats.

Shelter Stacks.—

"D. K. W." recommends that where hay must be stacked and fed out without removing it to the barn, the stacks be built in the form of sheds, to give shelter to cattle which are to consume the hay in winter. He says it can readily be done by making a rough frame of timber or rails, on which the hay is to be stored. We consider the plan objectionable, because the enclosure would be liable to become filthy without great care; there would be insufficient ventilation, and the odors arising from below would make the hay unpalatable and unwholesome. If the hay cannot be drawn to the barn or sheds and fed out there, better erect temporary shelters near the stack. No one but a shiftless farmer would think of letting cattle remain without shelter, and lie around the stack all Winter. A few uprights of poles, with a roof of rails, and a covering of straw or poor hay would amply repay for the trouble of building, if nothing better could be had.

The Peeler Plow.—

To many inquirers. This affair first came up in an offensive manner. Mr. Peeler, said to be a Southern clergyman, pressed it upon manufacturers with the specious plea that the Bishops and clergy of the largest and most influential Church in the country would all act as friends, and indirectly, if not directly, as agents, partly from sympathy with a brother minister, and more especially because he was making immense donations of the (prospective) profits to the educational institutions of that church. But notwithstanding this, we gave the plow a somewhat careful examination, and found it to be a rather rude conglomeration. The main idea was, to have a variety of mold-boards, land-sides, points, etc., all to be attached to the same beam, as wanted. The arrangement, if well executed, might answer for light soil, but the attachments were not firm enough to stand the rough usage of heavy or stony land. Deeming it of little practical utility, and disapproving of the effort to turn religion to money making account in so direct a manner, we passed the thing over in silence, and only make this note now in response to a great number of questions that have accumulated during some months past. Mr. Peeler is probably now among the rebels; happily he carried little with him from Northern manufacturers, who were somewhat taken with his promise of ministerial agency. If any of the Institutions of Learning have received a first instalment upon the splendid subscriptions made by him, we shall be happy to hear of the fact.

Manuring with Brains.—

If any of our readers happen in the vicinity of Ellenville, Wawarsing Township, Ulster Co., N. Y., we advise them to visit the farm of Mr. Joseph H. Tuttle, and see what the application of intelligent thought, of "brain manure" as our friend 'Squire Bunker would say, will do for a farm. They will see stony, hilly land, with wet bogs between the hills, converted into a fertile, paying farm. Draining on the side hills arrests the surplus water, and where only bog grass would grow, and where cattle would mire out of sight, may now be seen luxuriant meadows of Timothy. There is a story in the neighborhood to the effect, that one of these wet spots, restored by draining, and liberally lined and manured, yielded last year about 15 tons of good hay on 2½ acres! Every year's crop will doubtless pay for the cost of the drainage. Mr. T. has been for many years a careful reader of the *Agriculturist*, and has practised upon the hints obtained from its pages—with profit directly to himself, and indirectly, through his example, to his neighbors. He endorses the teachings of the *Agriculturist* almost as a whole, draining and all, but takes exception to our advice in regard to laying stone-drains with side stones and cover. He tried these, and they failed. He now drains wholly by setting the stones on edge in the form of an inverted v, thus , with oobble stones against them to hold them in place. We examined the drains June 9th, and though in the middle of a severe drouth, a stream of pure water flowed from the different drains, showing the necessity of their construction, even on hill sides which would usually be thought the last land to need draining. Mr. Tuttle raises roots for his stock, cuts all the feed, and steams it. He fur-

nishes dumping ground for the scavengers, or night soil gatherers of the village, and pays them liberally for depositing this material upon his farm, where it is mixed with muck, and converted into a valuable home made poudrette. We had not time in our brief chance visit to note down the items of cost, etc. Will Mr. T. give our readers some account of his mode of raising, storing, and feeding roots, straw food, etc. We know from his neighbors, that he makes his farm pay, and others would like the particulars, as to how it is done.

Apparatus for Drying Fruit.—

John Kostenbader, Lawrence Co., Indiana. A simple cheap apparatus by which fruit could be dried expeditiously and well, would undoubtedly be very useful, and profitable where the operation is to be conducted on a large scale. Its patentability would depend upon its novelty and superiority over methods at present used.

To Draw a Spike.—

Chauncy Lynch, Rutland Co., Vt., writes to the *Agriculturist*, that a tight spike may be withdrawn from the wood, by holding a sledge hammer, or the head of an ax, against one side of the projecting part, and striking upon the opposite side with a hammer. The blow should be an upward one against the under side of the spike head, if practicable.

Cabbage Puller.—

M. Scougale, Mich., says in reference to the cabbage puller, figured in the March *Agriculturist*: "I think a hook made from a small sapling is as good as any. The pole should be about 5 feet long, with a limb about 5 or 6 inches from the end. This is more easily made than the other and is just as good."

Accounts with the Farm.—

H. Baker, Mercer Co., N. J., suggests that farmers should keep a regular account of everything sold from the farm. He gives the proceeds from six cows for one year as follows: Butter 490 lbs. \$103.08; calves sold \$26.83; Alderney calf raised, \$25. Total \$159.91. Besides the butter sold, the family table was well supplied. If in addition to a record of receipts, there be also kept an account of expenses, the showing will be more valuable. It is desirable to know both profit and loss on all farm operations.

To prevent Chickens from Scratch-

ing.—G. W. Kitterman, Wapello Co., Iowa, writes that all trouble may be prevented by tying a forked stick 4 or 5 inches long upon each leg. "Have the stick long enough, so that there will be more weight on the hind part than on the fore part, and when the chickens go to scratch they will find themselves walking away, if the sticks are heavy enough behind."

Soaking Seeds.—

The Chinese seldom sow a crop without having previously soaked their seeds in diluted manure, keeping them there even until they begin to sprout. They hold that this not only gives the plants an early and vigorous start, but preserves the seed from worms or birds. The practical results of Chinese agriculture are too important for us to speak of them with contempt. Would it not be well for us to use some safe steps for our corn, squashes, melons, etc., as a general rule, and not as an exception?

Pruning Trees to Good Form.—

Too little attention is usually given to the formation of a good head, in pruning fruit trees. Begin as soon as the tree is planted, and use only the pruning knife. Never allow a tree to become "crothed," as it will be liable to split down. Rather encourage several branches upon different sides to preserve the balance. It is easy to start a branch to fill a vacancy, by cutting back a limb close to a bud at the point where the new one is required.

Summer Queen Apple.—

Dr. Ward, of Newark, N. J., spoke highly of this apple at the late Fruit Growers' Meeting. He kept an account of the sales from two trees one season, and they footed up \$60, selling from \$2.00 to \$2.50 per bushel. Being a large showy fruit, and ripening by the middle of August, it commands a ready sale at high prices.

Winter Mulching Peach Trees.—

M. Gookins, Fountain Co., Ind., writes to the *Agriculturist*, that for several years past he has each Fall placed around his peach trees a layer of half decayed straw about six inches thick, and extending three feet each way from the trunks. This was done to prevent the swelling of the buds during temporary warm weather toward Spring, by which much fruit is annually destroyed. Recently the peach trees in his neighborhood have been affected by the "Curl," a disease or blight causing the leaves to shrivel and the trees to die; but those which he has mulched as described above, have remained entirely free from this ailment. The cause of the "Curl" is not

well understood, but the prevention here indicated is worth trying elsewhere.

Natural Peach Trees not Health-

iest.—Thos. Roberts Jr., of Monmouth Co., N. J., the heart of the peach growing region, says that his experience, and that of others in the neighborhood, is, that natural peach trees are more subject to the "yellows" than huddled trees. He planted both side by side and the worked trees were every way the healthiest.

Curl on the Peach.—

P. A. Beffens, Florence, Ind. The specimens of peach leaves were affected by the Curl, a common disease in both this country and Europe. Some writers ascribe it to the puncture of a minute insect, while others consider it to be due to sudden changes of temperature, and most liable to appear when warm and damp days are succeeded by a comparatively cold spell. We have made several examinations and have never been able to find any insects. It is a subject upon which there seems to be very few accurate observations, and we have never known any remedy to be suggested. The diseased leaves soon fall and are succeeded by a new growth. If this is often repeated the vigor of the trees will be impaired.

Cutting Buckthorn Hedges.—

B. Kimball, Kennebec Co., Me. Your hedge set out last Fall with plants fourteen inches high, should have been cut back in the Spring to six inches, so as to form a thick mass at the bottom. Cut hack to ten inches now.

Chinese Chrysanthemums.—

Is it known to every one that these plants can be raised from cuttings about as easily as willows? That they bloom abundantly and continue at it from November to Christmas? That after a short rest, if the tops are cut off, new shoots will start up from the roots and bloom again in houses in March? And then, what a variety of colors and shades! Everybody should grow chrysanthemums.

Crocus—When Planted.—

Media, Wayne Co., Pa. The bulbs should be planted in September or October, at which season they are for sale at seed stores.

Camellia.—

"E. F. S.," Canajoharie, N. Y. The Camellia will not hold its buds in a hot, dry room. Try it in a room where there is no fire, and no freezing.

Lemon Tree.—

Mrs. G. B. W., Meadville, Pa. The tree would probably bear in time, but will do so much earlier, and bear better fruit, if budded or grafted. The best way is to send it to some experienced florist.

Mulching Strawberries.—

Irene Cole, Ind. Our best fruit growers put on a mulch of long straw in the Fall, opening it over the crowns of the plants in the spring. We have never heard of any injury from mice, resulting from this treatment. Take up Tiger Flowers and Tuberose after frost kills the leaves.

Books on Fruit.—

David Templeton, Crawford Co., Ill. A good work on Fruit Culture is "Barry's Fruit Garden"; the best descriptive work on Fruits is "Downing's Fruit and Fruit Trees of America." Any one largely interested in Fruit Culture should have both these works. We send them (post paid) at \$1.50 and \$2.

Plants for a Name.—

I. L. Herricks, St. Joseph Co., Mich. The leaves sent here are not the Silver Maple, but the Abele or White Poplar (*Populus alba*). It is a rapidly growing tree and a very showy one from the strong contrast between the green upper surface and white underside of its leaves, but it is a great nuisance on account of the numerous suckers it throws up from the root. Some of the small parks in New-York have the grass quite ruined by the abundance of these suckers. In streets, where the pavements keep them down, this is not so strong an objection.... F. C. Campbell, Pulaski Co., Ind. The plant sent is the American Columbine (*Aquilegia canadensis*). It is very common, and hence we rarely see it in gardens, yet it is much more graceful than any of the imported species.... Irene Cole, Ind. The specimen is the "Star of Bethlehem" (*Ornithogalum umbellatum*). It is sometimes cultivated in old gardens, but in many of the Eastern states it has become naturalized and grows wild. The true Snow Drop is a very different thing.

Gloves for Chapped Hands.—

Buck-skin gloves do very well in dry weather, but are poor things when wet. India-rubber gloves are used to some extent, and have the merit of being waterproof.

Brooklyn Horticultural Association. We regret that the Summer Exhibition of this heretofore enterprising Association must be regarded as a failure. The show of flowers and fruit was not larger than should be looked for in a town of five thousand inhabitants, while it is well known that the public and private Horticultural establishments of Brooklyn are excelled by few if any cities in the Union. There is either a great lack of public spirit on the part of cultivators, or culpable mismanagement by the officers of the Association. Wherever the fault lies, it should be corrected at once. The public taste, no less than the interest of horticulturists, demands that there should be a yearly exhibition of the progress made in this most delightful art. We trust that when the time for the Fall meeting arrives, it will be found that the present difficulties were only temporary, and that the Society may resume the position it was attaining, as one of the most successful institutions of the kind in this country.

Watering Growing Fruit.—E. D. Wisner, Monmouth Co., N. J., writes to the *Agriculturist* that fruit can be greatly improved when near ripening, by frequent and copious watering of the plants, unless there be abundance of rain. Where extra specimens are desired for exhibition or otherwise, they may be stimulated to larger growth by weak liquid manure. The watering should be done late in the afternoon, and mulching with straw, or freshly cut grass, tan bark, or other material, will aid in keeping the ground moist, and prevent baking during hot sunshine.

Apples Preserved in Sand.—John Firth, Center Co., Pa., recently sent to the office of the *Agriculturist*, (express paid,) a box of beautiful apples, whose natural period of ripening is in December and January. They were perfectly sound, and their flavor unimpaired. They are part of six barrels which were kept equally well, not twenty of the whole being unsound. They were picked Sept. 1st and 2nd, kept upon the floor of a room in the house about two weeks, and then packed in barrels with dry sand obtained from an iron foundry, which had been used in casting, and from which all vegetable matter had been burnt out. They were placed so that no two apples came in contact, each being entirely surrounded by the sand. The whole were then stored in the cellar. Mr. Firth thinks the remainder of the fruit will keep in good condition until next September. It would be easy to prepare sand for this purpose by burning, and the experiment is worth further trial.

The Best Turnip for Winter.—Charles A. Foster, Bergen Co., N. J. The Long White French Turnip is the best we know of for winter use on the table, and equal we think to any for feeding out. Its keeping qualities are unsurpassed. The general crop may be sown from June 15th to the middle of July.

Benefits of Frequent Plowing.—John T. Smith, Harrison Co., Ind., in a communication to the *Agriculturist*, says that throughout that section corn is generally backward; but that he has observed those fields planted early and plowed thoroughly through wet as well as dry times, are invariably good. The soil on the Ohio Bottomlands admits of this, and plowing before the ground is dry, prevents its baking and becoming cloddy. The average depth of plowing he says is 9 to 12 inches, and the yield of corn about 80 bushels per acre. Observing cultivators will "put that and that together."

Sulphuric Acid for Stumps.—Ebenezer Walker, Saratoga Co., N. Y. We have seen an item going the rounds of the papers saying that a stump might be quickly rotted by boring a hole in the top and filling it with sulphuric acid (oil of vitrol,) but it would probably be a failure. The acid would cause the parts with which it came into immediate contact, to decay rapidly, but it would not be likely to affect the roots by which the stump is anchored to the ground. A good stump-puller is more certain in its operation.

Soil for White Clover.—Alfred L. Waite, Potter Co., Pa. White clover thrives best on a soil containing a large portion of clay, and abundance of vegetable matter. It is abundant throughout the Northern and Middle States, where it makes the best of pasture, and is of great value for furnishing supplies to bees. The honey made from the blossoms is of the very best quality. Seed of the white clover is usually kept on sale at all the Agricultural warehouses and seed stores.

Honey for Market.—William S. Twining, Greene Co., N. Y. Boxes with glass sides in which the bees have stored honey are the best packages in which to send it to market. The purchaser can see the quality of

the article, and if white and clear, its inviting look gives it a ready sale at good prices.

Tomatoes in Pots.—Mrs. E. M. Wendall, Marquette Co., Wis. Tomatoes grown in pots where their roots have not room to extend freely, are dwarfed in their growth, and forced into earlier bloom and bearing. This method may be practised where a limited supply of extra early fruit is wanted, but it would not be profitable for a general crop.

Fig Trees—Where to Get.—L. C. Derby, Perry Co., Ill. Such extensive nurserymen as Ellwanger & Barry of Rochester, and Parsons & Co., Flushing, N. Y., and several others, raise fig trees for sale.

Keeping Wood Ashes.—D. M. Fisher, Blair Co., Pa. Wood ashes should be kept nearly dry; any water draining off, would cause a loss of potash.

An Excellent and Timely Machine.—We are glad to know that the improved flax brake made by Sanford and Mallory in this city is meeting with public favor, particularly as those parties who have put it to practical use declare it to be superior to any invention heretofore made for the same purpose. The importance of a machine by which the flax straw, now wasted, may be turned to account to supply the deficiency of cotton, can hardly be overestimated. On the article of paper alone there would be saved millions of dollars to publishers and to the community, by the general use of such a machine to work up tangled flax into paper stock. The proprietors are manufacturing small machines to be run by hand, which may be desirable in many localities. As their orders are already ahead of the supply, parties needing one of these machines should make early application. Full particulars are given in their advertisement on another page in this number.

Home Made Brooms.—George T. Weston, Rensselaer Co., N. Y. A better article of brooms can usually be had from those who make a business of the manufacture, and a ready market for broom corn can be found at such establishments. Full directions for making brooms, with ample illustrations, were published in the *Agriculturist*, Vol. xix. page 13, (January No.)

Sewing Machine Humbug.—A. J. Duncan and others. This matter has been referred to in the *Agriculturist*, but a further word of caution is not superfluous, as we notice certain parties are sending out great numbers of circulars to persons unknown to them, asking them to become agents, but requiring them first to send money to pay for a sample machine. Reliable concerns do not transact business in this manner. When they want agents, they take pains to know their men. It is of little use to correspond with such establishments. Let their circulars be turned to account as waste paper.

Sewing Machine.—"Subscriber." The "United States" sewing machine uses a single thread.

How to Make Money.—Irving Sead, Oconto Co., Wis., says this can be done by subscribing for the *American Agriculturist*, and gives the following statement in proof. "Subscribed in October, and received one map worth 25 cents, two extra numbers 20 cents, four papers of seed 20 cents; procured one new subscriber and received grape vine 50 cents; making a total of \$1 15, or 15 cents clear gain in addition to the paper for a year for nothing!" A pretty good showing truly, but not more than the facts will warrant, as thousands more will testify.

Advertising Doctors.—Notwithstanding all we have written on this subject, we receive frequent letters of inquiry about one or another of the hundred Doctors, who advertise themselves as having wonderful skill in curing specific disease—of the lungs, of the eyes, of the ears, and of every other human organ, or part of the body. We can not answer all these letters in detail, but will say, in general, that nearly all, if not all of these medical advertisers are quacks. We do not know of one of them to whose care, or prescriptions, or medicines we would entrust a friend. It is exceedingly easy to get up recommendations, and cases of extraordinary cures. There are certain instruments, or mechanical contrivances, such as artificial limbs, etc., which are properly advertised, where their utility is obvious. But not so with secret remedies, and the professed extraordinary skill of self-styled doctors.

"Head Quarters of the Pantarchy."—A "Friend" sent us sometime since a circular and letter dated as above, which had been directed to him by one "David Hoyle, Chief of the Bureau," and we are

asked to explain it. We have brooded over the said letter and circular a long time, and have at last hit upon the explanation as clear as mud. Here it is: Some abnormally inde-pre-disposed amorissimus d'argent et d'or, wishing to get money without working for it, has set into most violent operation his twitified cerebellum aut cerebrum, and hatched out a hexagonal hebdomadal mostest incomprehensible "Grand Planetary Governmental Organization, based upon the rapid approach of the Millenium, through the Marriage of Science with Religion, ultimated in Practical Life, etc., etc.," and "in each case a postage stamp must be enclosed, in addition to any contribution for the support of the Bureau."—The explanation is as clear as the "circular," and we don't ask a postage stamp for giving it.

Those Who Have Poor Teeth are to be pitied, whether the defects are the result of imprudence, or are inherited, as is so often the case. Poor teeth are not only the source of pain and annoyance, but where defective "grinders" or sore teeth prevent thorough mastication of food, the stomach is over-taxed, and indigestion and other diseases are pretty sure to follow. The Dentists are doing much to remedy these evils, and they could do more if people generally better understood the nature of the teeth, and the operations upon them. Skillful, honest dentists prefer to meet with intelligent patients. The above was suggested by reading a pamphlet on the subject by Dr. John Allen, of 22 Bond Street, N. Y. City, in which he gives some valuable information. The pamphlet was prepared with special reference to Dr. A's improved process of inserting teeth, but that does not detract from the value of the information given, and as the pamphlet is furnished free to all applicants, we advise those having poor teeth to send for a copy. We repeat what we stated last year, viz., that teeth inserted by the method of Dr. Allen, exceed all others we have ever seen, not only in beauty and natural appearance, but in effectiveness. We know of one set inserted by him that a thousand dollars would not buy.

Thanks to the Ladies who have contributed so many valuable recipes, items, and suggestions for publication in the Household Department. From the large number received, those are selected which are thought to be of the greatest general interest, and none should feel slighted because their communications do not appear. There are yet thousands of hints which might save time and money to many families, if the good housekeepers who read the *Agriculturist* would contribute them for the general benefit. Please choose your own subjects, write plainly and briefly, and receive the thanks of the community and of the Editors.

Stenographic Books.—G. O. Southwick, Tolland Co., Conn. Towndrow's work was formerly considered as good as any stenographic book, but it is now almost entirely superseded by Pitman's Phonography. Graham's Hand-Book of Phonography, published in this City at \$1.50, is a good American work.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed upon our tables since our last report.

FRUITS, ETC.—*Strawberries*:—Hovey's Seedling in pots, G. Nichol, Richmond Co., N. Y. Triomphe de Gand, superb specimens, C. S. Pell, N. Y. Orphan Asylum. Burgess' Seedlings, viz., Garibaldi, Gen. Scott and Gen. Lyon; White Pine Apple, Lennig's White and Albion, Wm. F. Heins, Woodstock, N. Y. Gen. Scott, Wm. A. Burgess, Glen Cove, L. I. Chorlton's Prolific, Wm. Chorlton, Staten Island, N. Y. Trollope's Victoria, very fine, Robert Bonner, New-York. Union Seedling, superior, S. R. Trembley, Bergen Point, N. J. Triomphe de Gand, 5½ inches in circumference, J. Corbett, Morrisania, N. Y. Cranberry Pippin Apples, very fine, R. Benner, Astoria, N. Y. Isabella Grapes, well preserved, Samuel Mitchell, Cameron Mills, N. Y. *Cucumbers*: Lord Kenyon's favorite, very fine, Anthony Boyle, gardner to W. P. Wright, Esq., Weehawken, N. J. Walker's Rambler, Mr. Erwood, Deer Park, L. I. **FLOWERS.**—Geraniums, Pinks, Pansies, and new Blotched Petunias, O. Judd, Flushing, N. Y. Clematis Sophie, beautiful blooms, R. J. Dodge, McClair, N. Y. Achysias, Cinerarias, Anaryllis, etc., C. S. Pell, N. Y. Orphan Asylum. Cut Flowers, A. S. Fuller, Brooklyn Nurseries, N. Y. Double Apple Blossom on present years' growth of wood, Samuel Havens, Westchester, Co., N. Y. Wax Flowers, beautifully executed, Miss Van Bergh, 1143 Broadway, N. Y.

MISCELLANEOUS.—Flax Cotton, Joshua Short, & Co., Little Falls, N. Y. Maple Sugar, very superior quality. Sample of White Poland Oats, four weeks from planting, very fine, George Lawes, Somerville N. J. Model of New Washing Machine, Wm. M. Doty, New York,

The Crop Prospects.

We present herewith a copy of the synopsis of the reports, as furnished us by the Agricultural Department at Washington. The plan of presenting the results is very simple and easily understood after a little study. A single figure presents the result of hundreds or even thousands of observations. Thus, for example, in the third column of figures against Iowa, the figure 12 tells us that the reports from fifty or a hundred persons in as many localities in that State, show, that the area of Spring Wheat sown in Iowa this year is two-tenths, or twenty per cent. greater than in 1862; while the figure 11 in the next column indicates that at the date of the reports the appearance of the crop was one-tenth, or ten per cent., better than the average of other years. With this explanation in mind, each figure in the whole table will become significant, and especially the general average at the bottom, for the whole country. The value of these tables will of course mainly depend upon the number of these reports, upon the good judgment and honesty of the reporters, upon the care in compiling them, and upon the promptness in publishing the results obtained.

Beyond all question, the Agricultural Department can confer a great benefit upon the entire country by an extended and properly executed labor of this kind. Millions of persons, farmers, grain dealers, the mercantile community, and indeed the whole country will, during the next three or four months, be anxious to know what are the condition and prospects of the growing crops generally. Farmers want to know whether the crop is to be an average one, or below or above an average, for the prospective prices will be materially affected thereby. If crops are poor, farmers will be less able to buy merchandise and manufactures, and less able to purchase freely, or pay up for past purchases from importers and manufacturers; there will be less grain to export and exchange, and indeed the whole fabric of trade and commerce, and even the National Finances, will be affected. And just the contrary result will be produced by unusually good crops; for, after all, the prosperity of the country depends mainly upon the absolute wealth derived directly from the soil. Hitherto we have been without any positive reliable information, except the reports gathered on the same plan last year by the *Agriculturist* office. We hope the new Department of Agriculture will spare no effort or expense to carry out, on an extended, comprehensive scale, the system of gathering these important statistics. Let them be so carefully collected and collated as to be absolutely reliable, and we can promise both a hearty cooperation, and the grateful appreciation of the entire country—not only of farmers but of all other classes. Comprehensive, accurate, and prompt reports of this kind, collected at the expense of a few thousands, or tens of thousands of dollars, as the case may be, will save many millions.

Of the *Crop Prospects Generally*, aside from what is contained in the Commissioner's report for May, we can not give as much information as would be desirable. The reports from the country at large, gathered from our own correspondence, and from some twelve hundred Exchanges, are very various. The general view is a cheerful one, but there are too many hints of late Spring, rain in some places, and severe drouth in others, to warrant us in saying that the crop prospects are the most favorable up to June 19th. In the immediate vicinity of New

The above table presents a very short abstract of the returns to the Agricultural Department, of the amount and condition of the crops in May, 1863. A fuller report, embracing other matter, will shortly be issued and sent to our correspondents and the press generally.—This table can readily be understood by all. The number 10 represents an average of the crops, both as to their amount compared with the crops of 1862, and their appearance in May, 1863. A number above or below 10, represents as many tenths as it is above or below it. Thus 8 is two-tenths below an average, and 14 is four-tenths above it.—The table is prepared by first taking an average from the returns of each County, and from these an average of each State, as published in the table.

WASHINGTON, D. C., June 15, 1863.

ISAAC NEWTON,
Commissioner.

York, the long absence of rain has materially damaged the hay crop, and lessened the growth of most other crops. Favorable weather hereafter may bring forward the cereals, for the rains we have just had, can not restore the stunted grass. The general reports are favorable for fruit. Our own personal observation, extending a hundred miles into Southern New-York, is that a comparatively small amount of fruit has set this year. The trees were everywhere full of blossoms, but a large proportion of them blasted. A similar state of things is reported from some other localities, while in others there has been abundance of rain, and not too much.

The Reports from Europe are almost as varied as from this country. Drouth has prevailed in many parts of Great Britain and the Continent, so much so as to tone down the exuberant feelings manifested about the first of May. The news by the last steamer is more cheerful than that received during the previous three weeks.

Millet Seed Injurious to Horses.

In the April *Agriculturist* "Basket Items," you say, that if Hungarian grass is fed with the straw it is generally thought to be safe. It is so far from safe, so really unsafe, I must write a word. Last Fall three horses were killed by it at one time from only once feeding. While waiting for a threshing machine to be set, an armful of it was given to them, and before another night three were dead and others made sick. I came very near losing a nice mare by feeding it one Winter. Four years ago almost every neighbor of mine used it for horses, now I know of not one that dare feed it. I could name a dozen horses in this vicinity killed, or nearly so, by using it. We never thresh it except for seed for sowing. Most here think that it is the seed that injures, and that when cut before the seed fills it is safe. Is it not the hull of the seed that irritates the coats of the stomach and intestines and thus causes disease? WM. B. REED.

[REMARKS.—So many have reported cases

similar to the above, that it would seem almost certain that for some reason, millet (Hungarian grass) seed can not be safely fed to horses. At any rate the safe plan on which all appear to be agreed is, to cut the grass for fodder before the seed is ripened, when it is to be fed to horses. For sheep or other stock, for all we have heard to the contrary, it appears to be desirable food.]

Reasons for Tillage.

Does any one inquire the reason why we plow, and harrow, and dig and hoe? A very sensible inquiry. We do these things partly in order to bring the ground into a proper mechanical condition for receiving seeds, and for growing plants. By the long continued falling of rains, the soil becomes compact and hard. So, also, the covering of a heavy body of snow in Winter brings the ground into a sodden and firmer state. This is the case especially on clayey soils. Run the plow, or work the spade through these compacted masses of earth, and it will render them porous, easy to till with the hoe, and prepared to receive whatever seeds we may wish to grow.

Then, again, tillage benefits the soil chemically. It opens the pores, so that it imbibes those fertilizing elements which the air contains. The atmosphere is a storehouse of carbonic acid and ammonia, but the earth can not be enriched by them largely, until its bosom is opened by cultivation. The soil, too, contains mineral and animal substances in a state of partial decomposition, which need the agency of the atmosphere to resolve them into good food for growing plants. Jethro Tull was no mere theorist.

So in reference to needful moisture. When the soil is well disintegrated, and the air enabled to circulate freely among its particles, there will be deposited a greater amount of water than in stiff, unbroken ground. And this moisture will be present just in proportion to the depth and thoroughness of the tillage. Hence it comes to pass that subsoiled lands seldom, if ever, suffer in the severest drouths. The air descending to the roots of plants, moisture fol-

The Harvest Field.

lows with it, carrying along ammonia to feed them with food and give them greater vigor. It is sometimes objected that very deep plowing injures a crop, by bringing up to the surface hard cold clay, which is hurtful to vegetation. Very true. Such plowing is hurtful, and we do not recommend it. The true method is to deepen the soil gradually, setting the plow point only an inch or two deeper every year. This will accomplish the end in a short time, and do no harm. The true method of subsoiling is to run the common plow first, then follow its track with the subsoiler, breaking up the lower stratum, but not lifting it out of its place. Or, as one says, "let it travel under the surface soil, as a mole might pass along without turning it over." And so in trenching land for gardening, the true way is, not to throw the bottom soil on the top in any considerable quantity, but to break up the lower stratum, mixing manure with it if convenient, and then returning it to its original place, cover it with surface soil.

Doubtless, many a farm which its owner considers nearly worn out, might be rendered fertile by deep plowing. The surface has been scratched over for many years, and this is indeed exhausted; yet underneath this, lie rich stores of productiveness as yet untouched. Not a few northern farmers have gone southward within ten years past, and bought up at a low price worn out land, and by good, honest plowing and subsequent tillage, have realized good crops for several years, and that too, without enriching with additional manure.

In England, six and seven inches in depth is considered fair and reasonable plowing, and subsoil work goes down eighteen and twenty inches. With us, the average depth does not exceed four or five inches, and subsoiling does not get deeper generally than twelve to fifteen inches. There is room for improvement here; and in due time we believe it will be made.

Harvest time, though a season of severe toil, is everywhere welcomed. Most other operations on the farm have reference to the somewhat distant future, when a return for labor shall be realized; but now, results are to be gathered. Each sheaf of ripened grain represents hours spent in plowing, seeding, and cultivating; and the swollen kernels remind the husbandman of the beaded drops of sweat with which he has often moistened the field. To the imaginative mind there are few more suggestive pictures than fields of grain white to the harvest. Each waving stalk is a rod of power, more potent than the magician's wand. It bears the elements without which commerce must stand still, manufactures perish, even war cease its fearful thunders, society become disorganized, and man utterly fail. But He who cares for man, has smiled upon the fields, and again they return a joyous thank-offering of plenty. But want of space forbids to pursue the pleasant fancies which this topic calls forth. Let us note a few practical suggestions pertinent to the season. And first with reference to the proper time of harvesting grain. Experiments have repeatedly proved that the weight and quality are both improved by cutting when the berry is just out of the milk, or as soon as it is hard enough to bear moderate pressure of the thumb-nail without breaking. This is usually about ten days before full maturity. A correspondent of the *Agriculturist* several years since experimented on a crop of fifty acres of wheat. The bulk of it was cut as here recommended, and weighed 62½ lbs. to the bushel. The remainder, gathered when fully ripe, gave only 58 pounds per bushel. On the whole amount of 1,200 bushels, there was a gain of 5,400 lbs., or about 90 bushels in bulk, and the quality of the flour was superior.

In addition to the difference in weight of the grain, there is no little loss by the shelling out of the kernels, when they are fully ripened. We have seen fields bear a large crop with no other seeding than that received from what had been scattered during the previous harvest. A still further saving can be made by going over the field with a horse-rake after the ground is cleared of sheaves. What is gathered, if not sufficiently clear for making flour, will serve a good purpose to grind into feed for swine and other stock. When, as at present, every pound of food is needed, and will command a high price, all should be turned to the best account.

There should also be an eye to the wants of the following year. In almost every lot of grain, on account of better soil, more favorable exposure, more thorough drainage, or other causes, some parts will give earlier maturity and a better yield than others. If pains were taken each year to mark such places and save the grain from them for seed, the result would be seen in a general improvement at harvest. The "Pedigree Wheat," which has become celebrated in England for its superiority, was produced by carefully following up this process for years. The cultivator, Mr. Hallett, took pains to select the best heads each season, and a marked improvement was made annually. So much pains as this can scarcely be expected during the present busy time, but the best part of the field can easily be marked off, and left to mature its seed. Before harvesting, the weeds should be pulled out, and when the grain is fully ripe, it should be gathered, and stored by itself, to be threshed with the flail, and used for seed. It would pay well in many instances to buy a patch from a neighboring wheat field, if it should be superior to any grown at home. The old rule "Take time by the forelock," so excellent to be followed in all farming operations, applies with especial force to the matter of securing good seed.

Hints for Haying Time.

In the great hay growing states, much of the crop will be gathered during the present month. It is noticeable that haying time has advanced during the last twenty years, it being now one to three weeks earlier than formerly. This has resulted, not from any change in the seasons, but from the growing conviction that a better article of fodder is secured by cutting grass before the seed has ripened. The *Agriculturist* has always sustained this view, and attention is again called to it from its intrinsic importance, and because a few yet remain who follow the old ways. It is generally understood that to secure the highest flavor and strength of medicinal herbs, they should be gathered when in flower, or just passing out of bloom; and accordingly careful housekeepers lay in their stock of boneset, motherwort, catnip, etc., at that period. When the seeds of plants commence to form, the nutritive portions are largely taken from the stem and leaves to aid in the development of this more important part—that which is to secure the continuance of the species. A further change also takes place in the composition of the stem, as maturity of the seed advances. A stronger stalk is needed to support the increased weight of the seed-bearing head, and accordingly, the sugar and starch are converted into woody fibre, which gives the required stiffness, but affords very little nourishing material for the use of animals. Grass forms no exception to this rule in the ripening of plants. Every one will readily notice the greater strength and harshness of a stalk of timothy when the seed is fully ripe. Animals are excellent judges in this matter; they will invariably prefer hay cut before the blooming season is entirely past, to that left to ripen its seed.

Much hard work and vexation will be saved by having all necessary implements in order before the labor commences. No thrifty farmer having ten or twenty acres of meadow will think of mowing by hand. If there be not work enough to warrant the purchase of a machine, arrange with a neighbor who owns one to have the work done. The horse-pitchfork will also be found indispensable after one season's trial. And once more we urge the desirableness of hay-caps. By their use many loads of hay may be saved from spoiling, and the whole crop be benefited by protection from dew while curing in the cock. A word or two on this latter point. In perhaps the majority of instances, hay is injured by too much exposure to the sun. In the haste to dry out moisture, a large amount of the sweetness of the hay is also lost. Grass cut after the dew is off in the morning (which can be done with the machine, but not well by hand) in fair weather, will be ready to put into small cocks before night. Cover it with the caps and leave it there two days, more or less according to the weather and convenience; then on a clear forenoon open the cocks for an airing of an hour or two, and they will usually be ready to draw to the barn. It is desirable to have several places for storing the hay, that not more than a load or two need be bulked at one time. It should not be packed tight, and ample provision should be made for ventilation. If there be any doubt as to the sufficient dryness of hay which it is desirable to put under cover, sprinkle over it three or four quarts of salt per ton, and spread a layer of dry, bright straw between each layer of hay made by an ordinary forkful. This will absorb a large part of the escaping moisture, preventing molding, and the imparted

flavor of the hay will make the straw itself palatable to stock. This plan of mixing straw with hay, while the hay is damp and green, is economical, as we know from successful experience.

How to Sharpen a Scythe.

"Mower" writes to the *American Agriculturist*: "To properly grind and whet a scythe, requires some little practical skill, in the attainment of which the beginner may be assisted by a few hints. The cutting edge of a scythe or similar instrument, when examined by a microscope, shows numerous fine projecting points or a series of minute wedges which are to be driven into the substance operated on, to separate the adjoining parts. In order that they may enter the more readily, these points should incline in the direction of the stroke given with the blade of the instrument. In cutting with the scythe, the edge strikes the grass at an angle of about forty five degrees, and hence the grinding should be done so as to have the points set in that direction to the blade. This is done by keeping the blade firmly upon the stone, with the point drawn toward the body of the holder, at the above mentioned angle with the edge of the stone. Commence to grind at the heel and move it steadily along as the work progresses, until the point is reached, then grind the other side in the same manner. Never rub the scythe back and forth upon the stone as though endeavoring to whet it. The revolution of the stone will wear away the steel much better than rubbing it in this manner, by which the edge is likely to be made rounding, and to be set irregularly. It is preferable to hold the scythe so that the stone will revolve toward the edge. In this way the holder can see when the edge is reached, and the particles ground off are carried away clean. In the opposite method of grinding there is danger of making a "feather" edge which will readily crumble off, and leave the scythe almost or quite as dull as before. The blade should be ground equally on both sides. In whetting a scythe, lay the rifle or whetstone flat against the side of the blade, and give a light quick stroke downward and forward, in the direction of the edge, so that the scratches it makes, shall keep the points set in the same direction as given them by grinding. By following these simple suggestions, a scythe may be made to hold its edge twice as long as when the rifle is drawn along the edge almost at random. A few strokes carefully given, will enable the workman to keep the right direction and whet rapidly."

Steam in the Hay Field.

To the Editor of the *American Agriculturist*:

Steam would be a capital thing in the hay field, no doubt, if it could be applied in the right place. There's a grand chance for some Yankee to invent a steam mower, raker, and pitcher, when this war is over and inventors have time to think of something besides guns and shells, and other man-killing traps. But I want to enter my protest against trying to make human engines work by steam in haying time, or for that matter, at any other time. A great many people yet have the notion that in haying time, whiskey, or elder brandy, or some other kind of steam as they call it, is particularly necessary. They can chop, or plow, or hoe, or do any other farm work without such help, but when haying and harvest commence, the jug must be

regularly filled and emptied. I don't know why they don't fire up their horses as well as themselves, especially since mowing machines have come into fashion, and animals have the hardest part of the work to do. For my part I think one needs it just as much as the other, and no more. It always appeared to me that a July sun was hot enough, without a man's pouring liquid fire down his insides. I know that after a dram a man will feel a little more like work for an hour or so, but its only doing so much overwork, and the hour afterward he will do underwork enough to more than balance it, and feel much more exhausted than if he had gone on at a steady gait without the extra steam. Alcohol don't strengthen the body, it only excites it for a short time, and makes it work faster and harder than its natural power would allow, and this over-exertion must be made up for by more rest afterward. If any one doubts this let him try it on his horse. Give whiskey with his oats, and see how he will make things go for a while, and how soon he will be used up afterward. Men would not do this for fear of injuring their animals; for my part I think man the most valuable animal on the farm, and what is not fit for a horse is not fit for him. JONATHAN.

[We fully agree with Jonathan, regarding the use of alcoholic drinks in the hay (or any other) field, but would at the same time caution against the excessive use of ice-water. Immoderate water drinking is quite as much the result of habit as of necessity. During the violent exercise of the hay field water is needed to replace that lost by perspiration; as a general thing too much is taken. A beverage of water, vinegar, sugar or molasses, and ginger, is much used in some localities, and is found to satisfy thirst better, and less liable to produce unpleasant consequences than large quantities of ice-water.—ED.]

Manure Making in Summer.

This is generally overlooked, in the press of field work which engrosses the attention of the cultivator during the Summer. Yet there are occasional hours which can be profitably employed in this work. Except where the natural fertility of the soil is for the present sufficient to meet all the wants of growing crops, other things being equal, the prosperity of the farmer will be found to maintain a remarkable ratio to their attention to enriching his land. We believe that on hundreds of farms it would well repay the cost, to employ an extra hand for the express purpose of collecting and preparing manures. The sources from which materials are to be drawn of course vary in different localities, but the principal ones are among the following: 1st, the barnyard. Where cattle are yarded at night, their droppings, if left uncared for, as is usually the case, lose a large part of their value, by drying out under the hot summer sun. Evaporation carries off much of the ammonia, one of the most valuable ingredients, and it is wafted along by the air to be distributed in infinitesimal portions over the surrounding country. The careful manager will provide muck, sods, soil, or other absorbent to mix with excrements every few days, either by shoveling over in heaps, or by plowing up the yard, which is more expeditious though less favorable to the cleanliness of the yard, where milking is usually done.

Along the roadside and too often by the fence-lines, are numberless weeds which have drawn part of their support from the soil, and gather-

ed the remainder from the air and moisture. They are stored with fertilizing material, and if cut and worked over by the pigs in the pen, or made into a heap with muck and lime added, will swell the store of grain and grass-making substances. The slops and refuse from an ordinary family, if properly economized, will furnish nearly or quite good manure enough to nourish the vegetables they consume. Usually these are worse than wasted by being thrown into some corner, where weeds grow rampant on the valuable deposit. Then there are the privies, the contents of which, if utilized by mixing with muck, or common soil, might add vigor to the growth of garden and field, but which commonly make their locality only a nuisance. Many swamps which are inaccessible at other seasons, can now be entered, to draw from them the accumulation of vegetable matter which has been gathering for many years. This only needs properly working over, to take a new form in grass, grain, fruit, vegetables, in short any desirable product on the farm. Cheap hands, such as could not profitably work at cultivating, can be hired to dig muck and throw it into heaps, to be acted on by the elements, and afterward used to increase the compost heap. All these sources should be turned to account during the Summer, even if extra help be required to accomplish it. If the *Agriculturist* should do no more than induce cultivators to turn their attention to the available supplies of manure and their proper application to crops, it would accomplish enough to many times repay its cost to the community.

Buckwheat versus Summer Fallow.

Summer fallowing, that is, plowing land in Summer and allowing it to lie unoccupied until sowing with winter grain, is practised by many for the alleged reason that it *rests* the land, and gives it heart for the next crop. It is enough to say on this point that land does not *tire* of producing. It needs only plant-making material enough in its substance, to continue to yield abundant and increasing crops. It is not required that an amount of manure be restored to the soil equal to the amount of produce removed, for a large portion of the substance of plants is derived from air and water. For this reason there is positive gain in allowing growth upon a field, if all the vegetable matter produced be returned to the soil. Summer fallowing is therefore, in one respect, prejudicial to the fertility of land. It may, however, secure other important advantages. It makes the soil mellow, and brings it into good condition for the reception of the fall-sown grain, and if properly performed, secures the destruction of many weeds, by exposing their roots to summer heat. But these ends can be equally well attained while raising a profitable crop of buckwheat. Provision should of course be made to feed the crop, if the grain is to be harvested. A moderate dressing of manure will be sufficient on land already in good heart. If there be not enough barn-yard manure, apply a good dressing of bone-dust or Peruvian guano. Plow early in July, which will eradicate most of the weeds, harrow thoroughly, and sow about three pecks of seed per acre. In a favorable season, the rapid growth of buckwheat will smother nearly all the weeds that have survived the preparation of the ground. In Autumn the crop may be harvested in ample time to prepare the soil for wheat or rye, the sods will all be well rotted, and the land in as good condition

after plowing as though it had *rested* during the Summer, while in an ordinary season, there will be 20 to 25 bushels of buckwheat per acre on the credit side of the account. This grain will also well fill the vacancy which may have been left by a corn crop failing through unfavorable weather or other causes in Spring. Buckwheat is always marketable. During the present and prospective high prices of oats, it will not come amiss for grinding and feeding to stock, and a liberal quantity for consumption in the house is always a welcome addition to the staple winter provisions.

For the American Agriculturist.

Shall the Clover be Plowed Under?

There it lies, a splendid field of clover, in full blossom, musical with the voices of myriad bees, and perfuming the morning air with its fragrance. It is altogether too handsome to be put under the dirt. You might go miles to find so fair a sight, even in a flower garden. And then if it were not, what thrifty farmer can afford to manure his field at such a cost? There is not less than three tons of cured hay to the acre, worth at least ten dollars the ton standing, to say nothing of the after feed which must be sacrificed to manure. Can a man afford to give thirty dollars an acre for manure? Mr. Pennywise hesitates, and thinks it is paying too dear for that whistle. He can get his manure cheaper. But can he? Let us look at it a little. What has the clover actually cost him? The seed, say one dollar per acre, the extra labor of sowing, and the interest upon the value of the land. As the seed was sown with oats or barley, or some other grain crop, we do not count the labor of getting it in. It has not cost him five dollars an acre, even if the land is worth sixty dollars. In the green state there are probably eight or ten tons of vegetable matter, equivalent to a heavy manuring with stable manure, that would cost thirty dollars per acre, reckoning the manure at two dollars a cord, and the carting at common prices.

The clover is just where you want it, and if turned in, will be more evenly distributed than any stable manure can be by the most laborious process. There is hardly an inch square of the whole sod that will not feel the effects of the decomposing matter. There is no expense for carting, for spreading, or harrowing. Then it is to be considered that it is not simply so much vegetable matter added to the soil, but added to it in a succulent state, in which it will be rapidly decomposed and changed into plant food. Green crops, turned under in the early Summer, affect the soil with which they come in contact in some way that we do not fully understand. Possibly the acids released act upon the mineral portions of the soil, and form new compounds that are immediately available for the food of plants. This seems to be necessary to account for the beneficial effects of plowing in at this season, rather than in the Fall, when the fibre of the grass is harder or partially dried. Experience shows that the crop has by far the best effect when it is turned under in the green state, and in warm weather. It goes through a very rapid fermentation, and in some manner changes the character of a good deal of soil with which it comes in contact.

If a farmer had all the manure he wanted, and his fields all lay close to the barn-yard, it might not be economical to turn in green crops, and especially clover which is so valuable for fodder both green and cured. But few farmers

have as much manure as they can use to good advantage, especially in the older States. Some of the fields lie at a distance from the barn, and the expense of getting the manure on to the ground is greater than the cost of making the manure. And even if manure were plenty, it is a good plan to have a place in the rotation, where a green crop is turned in. It does a good work for the soil, that can be accomplished by no other method so economically. It makes a splendid seed bed, and prepares the ground for winter grain in the best manner.

It seems a great waste to spoil so much good food for beasts, but it is in keeping with the economy of husbandry. It seems a great waste to put eight or ten bushels of potatoes in the soil to get a crop; but they come back again many fold. That which we sow "is not quickened except it die." The seeming losses of the farm are often our largest gains! If we are charmed with the blossoms and the murmur of the bees, better close our eyes and stop our ears, and let the plow do its work. New life and vigor will be imparted to the soil, and there will come up out of the grave of our buried hopes, a glorious resurrection—fields of tasseled corn or golden wheat to make glad the heart of the husbandman.

CONNECTICUT.

Sheep as Fertilizers.

John E. Traver, of Dutchess County, N. Y., writes to the *American Agriculturist*: "I keep a flock of thirty sheep which have had the range of an eight acre lot. The soil of this was thin, as it was situated at some distance from the barn-yard, and had received no manure from that source. In the Summer of 1858 the dogs got among my sheep and frightened them so they would not go on the back side of the lot, unless it was to feed for a short time, and they lay wholly on the one side of the field. I planted it with corn after it had lain two years. The side of the lot where the sheep had rested, gave a good yield, and the worms did not trouble it throughout the season. Where the sheep did not lay, but only fed, the worms made sad havoc, and the corn was poor. The oat crop following showed the same difference. On the rye I did not see so much inequality. My opinion is that if we keep more sheep, our crops will not be so much infested with worms.

Tanning Skins of Animals.

"D," of Jackson Co., Ill., writes to the *Agriculturist*: "Old hunters here tan hides and skins of all kinds with *brains*.—A new use for brains, you may say—but a better use than *some brains* have been put to, for a year or two past, at least. If the hair, wool or fur, is to be retained in the skin, it is simply soaked in warm water and the fleshy part rubbed off with a knife, the skin being stretched over a half round block for convenience. It is then soaked a short time in a little water in which the brain of some animal is dissolved; then taken out and pulled and stretched every way until dry. It will then be soft, pliable, and not liable to become hard on being wet and drying again. If I remember rightly, the lime process is adopted to get rid of the hair or wool, after which the skin is very thoroughly washed to get all the lime out of it, and then manipulated with the brain water."

QUESTION FOR THE N. Y. FARMERS' CLUB.—Will wheat *blast* more easily for being drilled?

Fig. 1.—COUCH-GRASS.

Talks About Weeds...II.

In these notes upon weeds we shall not follow any botanical order, but take them mainly with reference to the season. The first one we notice is Couch grass, (*Triticum repens*), fig. 1, which is, in some localities, a most troublesome weed. Where it gets full possession of the ground, it will overrun and occupy it to the exclusion of every thing else. It is also known in different sections as: Quack-grass, Quitch-grass, Twitch-grass, Dog-grass, Wheat-grass, etc. The last-mentioned name is given from its resemblance to wheat, both belonging to the same genus. The stems are about two feet high, and bear a head somewhat like that of wheat, though longer and more slender. Unlike wheat this is a perennial, and one of its most remarkable characters—that which makes it so difficult to eradicate—is its long underground stem, which is commonly mistaken for a root, and runs just below the surface. This underground stem throws out roots from each joint, and has at the same point, a bud or eye from which a stem may spring. It will be seen that every inch or so of this stem is capable of becoming a plant, as shown in fig. 2, which is a rooted layer—a piece of stem with a root and an eye ready to start. This explains the great difficulty in exterminating Couch-grass.

Fig. 2.

If the cultivator is run through a tuft of the plant, it may tear away the above-ground portion, but there will be left below, a large number of fragments of these underground stems, each one of which will make a new plant. From the manner in which the plant multiplies, it will be seen that merely scraping the surface with a hoe will not destroy it; this only causes a dozen plants

to spring up where there was one before, and the work will shortly have to be done over again. There must be no half work, for nothing short of actual eradication will get rid of it. Perhaps the best plan is to run a cultivator through the soil and follow it with a fork, and carefully pick out all fragments and lay them in the sun to dry. With this, as with all troublesome weeds, much labor is caused by neglect when the plant first makes its appearance in the fields. A few weeds do not present a formidable appearance, but they are quietly laying the foundation for much after trouble. In some parts of England, a large part of the expense of cultivation is due to the labor devoted to the eradication of the Couch grass. The grass is liked by cattle, and it is raised in some parts of the South for pasturage.

BIND-WEED.—We introduce here a figure of a weed which is exceedingly troublesome in Europe, and which has become established in some places in this country. We have some native plants which are called "bind-weeds," but the name properly belongs to this—the *Convolvulus arvensis*. The plant is very much like a small Morning Glory, to which it is closely related. The stem grows two feet or more high, and twines around other plants. The shape of the leaves is shown in the figure, which is about half the natural size. The roots are perennial, and very long and very difficult to destroy. It soon spreads rapidly, and should be exterminated, at whatever cost of labor, as soon as it makes its appearance. It comes from Europe, but we have a native plant which is a near relative, known as the Wild Morning Glory, and Large or Hedge Bind-Weed. This is much larger than the other, and will run to the height of 8 or 10 feet. The flowers are about as large as those of the common Morning Glory. It

Fig. 3.—BIND-WEED.

grows in low moist places, and sometimes becomes troublesome in cultivated grounds. Frequently repeated hoeing down is the only successful remedy which we have seen suggested.

Sugar from Unripe Cane.

L. F. Hadley, of Chicago, Ill., who has had considerable experience with the Chinese Sugar Cane, says, in a communication to the *Prairie Farmer*, that the time to make sugar, commences when the cane begins to mature, and ends when the cane is fully ripe, after which it will make good molasses, but not sugar. Several years' trial has convinced him that this is the case, and in illustration he gives the results from cane cut just as the seed was beginning to turn brown,

which granulated finely, while the syrup from the rest of the field, cut when fully ripe, refused to "sugar off." He recommends to cut early, and work it up as fast as possible, but thinks it will make sugar late, if cut before fully ripe.

Testing the Quality of Milk.

The real value of a cow to the dairy farmer is not in the number of quarts of milk she will give, but in the number of pounds of butter she will afford. There is a greater difference in this respect than is generally supposed; some

Fig. 1.—LACTOMETER.

cows making twice or even three times as much butter as others. Several methods have been proposed for testing the qualities of milk,—one of these is by the use of the hydrometer. The construction of the instrument will be understood by the engraving, (fig. 2.) A small glass tube, with a bulb at one end, has a wooden float fixed upon it. Shot are placed in the bulb in sufficient quantity to sink it in water to the point marked 100 on the stem. The instrument is then put into pure milk, and the point at which it stands in that, is also marked on the stem, and the place between the two marks divided into 100 degrees. As pure milk is heavier than water, the instrument will be buoyed up more in the one than in the other, and it at first sight would appear to show the value of the milk. But the specific gravity of cream is less than that of milk, and a specimen of milk very rich in cream, would show lighter by the hydrometer than a poorer sample. Though this instrument would be serviceable to the city consumer in detecting adulteration with any considerable amount of water, it will not serve the dairyman to indicate the butter-producing quality of the milk of different cows. The old lactometer, which was invented a half century ago, has not been superseded in practical worth by any recent contrivance. This tests the value of the milk by showing the amount of cream afforded by each sample, and consists, (fig. 1,) of a series of glass tubes of equal size, closed at the bottom; they are about a foot long and one third of an inch in diameter, and graduated by markings on the glass. These are to be filled to an equal height with milk, and after standing for the cream to rise, the comparative value of the milk of different cows can be seen at a glance. An apparatus of this kind is not only useful as showing the difference in cows, but also in testing the butter-producing value of different kinds of feed. These tubes are cheap, and may be bought at most of the agricultural warehouses.

Fig. 2.

The Balance Gate.

The farm gate illustrated above, the description of which was communicated to the *Agriculturist*, by N. Hine, Atlantic County, N. J., possesses some excellent features. It is a modification of the well-known, old-fashioned balance gate. The construction will be readily understood by reference to the illustration. The beam or pole *A*, of suitable length, turns on the post *E*, being held in place by a 2-inch pin extending through the beam. The uprights, *B*, 2x3 inches, pass through mortises in the middle of the beam, and are pinned fast. The slats, *C*, are of boards of any desired width, securely fastened to the uprights with wrought nails clinched. When the gate is closed, the smaller end of the beam rests in a slot or mortise in the post at *F*, or a strip of plank with a suitable notch for the purpose may be pinned to the post. A narrow strip, *G*, hanging from a pin at *H*, rests over the end of the beam, to hold it in place; this is turned aside when the gate is to be opened. The gate may be balanced by placing weights upon the short end of the beam, at *I*, so that a very small amount of force will turn it. It opens in either direction, can be easily lifted over snow drifts, and what is of great importance, the weight of the gate can not draw the supporting post out of perpendicular.

The Barometer as a Weather Indicator.

Careful observations through many years and in different countries, have established the fact that a change in the weather is generally foretold by the barometer. Recently some persons have endeavored to throw doubt upon the value of this instrument as an indicator of the weather, but until we can see their written observations and a record of the state of the weather at each observation, we shall continue to believe with the majority of meteorologists—especially as our own experience coincides with theirs. That the barometer, properly understood and observed, will in the great majority of cases, foretell a storm, we are confident—not from a few observations, but from watching it for several years, and in different climates. One thing which has brought the instrument into disrepute is the practice, followed by many makers, of marking upon their scales “fair,” “change,” “rain,” etc. Persons finding that the mercury seldom indicates the weather according to these markings, have given up the instrument as altogether unreliable. The value of the barometer (unlike the thermometer) does not consist in showing where the mercury stands, but in showing the change which takes place in its height from one time to another. It is the *rise and fall* of the mercury which is to be observed, and the extent of this varies in different sea-

sons, and in different localities. To derive any benefit from the barometer, it should be observed at fixed periods—(7 A. M. and 2 and 9 P. M., are the usual ones)—and the observations recorded. It may be stated, as a general rule, that if the column remains for a long time at one particular height, we may expect a continuance of the present weather, be it good or bad: if the mercury suddenly falls, a sudden change of weather, but of short duration, may be looked for: a gradual sinking of the mercury, for one

notes upon the state of the weather are given, in condensed form, at the bottom of the diagrams.

During the month of February, the fall of rain and melted snow amounted to 7.04 inches. The mercury in the barometer, on the 5th, rose to the highest point reached in 30 years. As a fall nearly always succeeds a rapid rise, upon seeing the mercury going up so rapidly, we confidently looked for the fall and rain, which came plentifully on the 6th. It will be noted that every considerable depression of the mercury, was accompanied by rain. It fell suddenly on the 19th, and reached the lowest point for the month. A heavy rain occurred at the same time, commencing with N. E. wind on the 18th, and ending on the 20th. The variation from the extreme rise to the lowest fall was an inch and-a-half, which is greater than the average.

Farmers well know that May was a *dry* month. There was less than half an inch of variation in the barometer up to the 30th, and less than four inches of rain, the most of which fell in the first half of the month. The track is the most even one for a whole year, though several rain falls occurred, some of which were not very clearly indicated by the barometer. The mercury began to fall on the 28th, and con-

or more days, foretells a long continued storm, and during a storm, a rise in the column shows the approach of fair weather. To show the correspondence between the height of the mercury in the barometer, and the state of the weather, we present two diagrams, which are actual transcripts of the records kept at the office of the *Agriculturist*. This manner of recording matters lia-

continued to sink until the 31st. We had fine showers the 30th and 31st. Our engraved record for May only includes 28 days to correspond with the month of February. It is only where the barometer is frequently watched, that its use is manifest. We conceive that it would be both interesting and profitable for the farmer's son, to keep an accurate record, not only of the ba-

ble to fluctuation, was described on page 44, February No., and presents the barometric variations to the eye in a striking manner.

In each diagram the perpendicular lines indicate the days of the month, while the horizontal ones mark the height of the mercury; each line represents ten-hundredths of an inch. The

rometer, but of the thermometer, and the state of the weather also. It is a matter of great interest, to compare one month with another, and one year with another. Our special premium now puts it within the power of most persons, to secure a reliable instrument on very easy terms. (See page 224 of this number.)

Notes on Cheese Making.

The more solid part of milk consists mainly of oily matter (butter,) and a substance named caseine, the principal ingredient in cheese. To make a good article of cheese for the table, requires that both the butter and the caseine be retained, and the watery portion or whey be wholly pressed out. Cheese can be made, as every farmer's wife knows, of sour milk from which all the cream has been removed, or from buttermilk. The solid part or caseine is easily separated from the whey by heating, and it is often prepared in this manner under the name of "pot-cheese," or "cottage cheese." In order, however, to make even this palatable, it is necessary to work in with it a portion of butter. Much of the cheese sent to market has been made from skimmed milk, and its toughness and want of flavor are in proportion to the amount of cream which has been removed from the milk. Some specimens might almost be replaced with India rubber, or gutta percha. It follows that to manufacture the best cheese, the cows should have good feed from which to elaborate rich milk. As butter readily receives any foreign flavor, pastures should be free from weeds, many of which impart an unpleasant taste to the milk and its products. All things considered, timothy and clover, either white or red, are the best staples from which to manufacture cheese or butter.

In making cheese it is desirable to add some substance to the milk to curdle it, or separate the solid portions from the whey, *before* the oily part or cream shall have risen, as it can never again be mingled with the caseine so intimately as it exists in the fresh milk. Various acids will effect this; the only one now used is that found in the fourth stomach of the calf, which consists of the gastric juice secreted by the coats of the stomach. Much of the excellence of the cheese depends upon the proper preparation of this article. It should be from a perfectly healthy calf, from one to six weeks old—about four weeks is thought to be the best age. When the animal is first killed, the stomach is opened and emptied of its contents, but not scraped or rinsed, as this would remove some of the gastric juice. It should be well salted and dried on a stick bent to its shape, in which form it may be kept in a dry place for a year or more. To prepare it for use, an ordinary sized rennet is placed in a gallon of soft water warmed to about ninety degrees, in which it is churned or rubbed occasionally for twenty four hours. After the rennet is removed, it may be dried, salted, and used again. To the rennet liquor is added as much salt as it will dissolve; it is then strained, and kept in tight vessels in a cool place to be used as wanted. A gill of this liquor will curdle thirteen to fourteen gallons of milk.

It is desirable in making cheese to have the milk all drawn from the cows at a single milking, but when this is not convenient, the evening and morning milkings may be used together. When this is done, set the evening milk in pans in a cool place, in the morning skim off the cream and add twice its quantity of hot water to raise the temperature to about 100° Fahrenheit, and stir until the whole is well mixed. Then add it, with the milk from which it was taken, to the morning milk, stir the whole together, and proceed as with a single milking. It greatly diminishes the labor of cheese making, and aids in securing a good article, to employ an apparatus specially con-

trived for heating the milk. There are several such, which consist mainly of a milk vat with double bottom and sides, the space between to be filled with water, to which heat is to be applied, thus avoiding danger from scorching, which would spoil the flavor of the cheese. The milk being ready, heat is applied to raise the temperature to about 90° Fahrenheit, when the rennet liquor is to be introduced and stirred until thoroughly mixed. In from forty to fifty minutes a firm curd should be formed. The separated whey is now to be drawn off with a faucet to within about an inch of the bottom of the tub, after which the curd is cut through perpendicularly and horizontally, with a wide bladed knife made for the purpose, into pieces about half an inch square. It is then to be removed to the strainer, which is usually placed in a basket, and set over a tub to allow the whey to drain out. After draining, it is returned to the vat, the whey first drawn added to it, and the temperature raised to about 100° Fahrenheit, to cook it before salting and pressing. It should be continually stirred until this process is finished, which is known by the curd becoming elastic, and breaking toughly with a sort of creaking noise. The whey is then drawn off, the curd allowed to cool, and salt added at the rate of one pound to thirty pounds of curd, to be worked into it thoroughly by hand. When the mass is fully cooled, it is to be pressed. The curd is placed in a clean linen strainer, confined by a hoop of proper size, and the press gradually applied to it, the pressure to be continued from three to six hours, according to the size of the cheese. It should then be turned again and pressed heavily for twenty four hours or more, when it is ready to be bandaged and laid upon the shelf. The bandage is simply a piece of heavy white cotton drawn around the circumference, and lapping over the top and bottom some two inches; it is kept in place by stitching with coarse thread. The cheese should then be laid upon a shelf broad enough to sustain its whole circumference, rubbed over with common butter, or that article mixed with whey butter, with a little cayenne pepper added to repel flies; turn daily until ripened. The temperature of the room where cheeses are first stored, should be kept up to about 80°. Of course the method here detailed admits of considerable variation, but these directions carefully observed, together with *cleanliness in all the operations*, will secure an article which will always find a ready market at good prices. *

The Cow-Milker Again.

This instrument which received such a large share of attention at the International Exhibition in London, and which it is said realized for its proprietor a very handsome sum by the sale of rights, did not entirely escape criticism from practical men. The editor of the Scottish Quarterly Journal, not content with merely inspecting the Yankee invention, and witnessing its operation when worked by others, made several trials of the apparatus, using it with his own hands and thus speaks of it: "At first we experienced some difficulty in using it. It is not as easy as might be supposed, to fit the finger-pieces on the teats air-tight; and when they are so fitted on, a restive animal is liable to throw the whole out of gear. We attempted the milking of three cows on the first trial. From one which was milking from 5 to 5½ quarts at a meal, we obtained 4½ quarts; another, which has very uneven teats, we could not milk

at all; and from the third, which was only milking 2½ quarts at a meal, we were only able to obtain a little more than a quart. All our subsequent trials have been attended with similar results. The conclusions to which we have arrived in reference to this machine, are:—

1. It will not extract all the milk from cows. If it should be found to answer in every other respect this is no fatal objection to its use, as the strippings could be milked by hand.
2. Cows that have good teats, well set in the udder, can be milked to within half a quart to a quart of their full milk.
3. Cows whose teats are uneven can with difficulty be milked.
4. We doubt very much if any amount of experience and preserverance will overcome the difficulty of milking kicking or restive cows."

For the American Agriculturist.

Improvement of Agricultural Exhibitions.

Agricultural Exhibitions should be something more than mere shows to excite and gratify curiosity. In conducting them, this has been the principal motive apparent to too great an extent, whether or not designed by those having them in charge. Of what practical value is it to a cultivator to look upon a bullock fattened to unwieldy proportions, or a beet or pumpkin grown to monstrosity? Such displays, it is true, call forth expressions of wonder, and are interesting as being out of the ordinary line, but for all practical purposes there would be equal benefit in examining Barnum's woolly horse. At the Exhibition of a County Agricultural Association held last year, and attended by the writer, the most instructive feature was a collection of samples of wheat, accompanied in each instance with a statement of the kind, time of sowing, method of treatment, period of ripening, and yield per acre. There was material enough in that corner for hours of profitable study, and a few knowing ones were busy there taking notes for future use. Without doubt many of their crops the present year will show that a most profitable day was spent at the exhibition. We insist that each article exhibited should be in itself an epitome of some valuable facts for cultivators, and that it should be accompanied with such written notes that the whole story could be readily gathered by the observers. It is comparatively easy to fit up a show specimen according to present methods. Plant a few hills of pumpkins on ground expressly prepared for the occasion. Select the most vigorous vine, leave only the most promising sample of fruit, prune the rampant growth, dose with liquid manure, and ultimately a monster may be the result. But who thinks this would pay in ordinary practice? And so of other agricultural productions. It may not be so attractive, but it is far more worthy attention to carefully conduct an experiment which, if successful, may be profitably repeated, and exhibit its results, and the details by which they were reached. It is pleasant and harmless amusement now and then to produce and exhibit articles of unusual proportions, but it is beneath the dignity of cultivators to allow such displays to be the chief attractions at their exhibitions. To a large extent the visitors at exhibitions are responsible for the mismanagement now objected to. They attend the annual agricultural gathering more with a view to sight-seeing, than of seeking improvement, and managers feel compelled to cater to their taste in order to raise the requisite funds for the support of the institution. Hence, the stimulus of prizes

for the largest and most showy articles, the patronage of the race course, and the tolerance and introduction of shows entirely foreign to the object of the meeting. It is fully in the province of the managers of Agricultural Associations to institute a reform in these particulars, and to educate the public to a just appreciation of the appropriate work of such Exhibitions, viz.; to show the proceeds of the best culture, and the methods by which all may secure like results. Farmers will gladly spend a few days and dollars if they can gather facts which shall increase their harvests or lighten their labors. It is not intended by these remarks to entirely condemn the present management of Agricultural Exhibitions in this country, but only to call attention to some growing abuses which threaten to bring these almost indispensable institutions into contempt. Taken as a whole, our Annual Exhibitions will compare favorably with those of any other country; it should be our aim not only to make them superior to others, but to raise them to the highest possible standard of excellence. OBSERVER.

Working of the Homestead-Law.

The following extracts from a familiar letter written by a subscriber to the *Agriculturist*, indicate how great a benefit has been conferred by the Homestead Law upon thousands who need only a start in life to become the independent possessors of a home and the means of support. Let those who from untoward circumstances find it impracticable or difficult to make their way by other means, find encouragement in the example here shown. The writer says: "I failed up in the mercantile business, had nothing left but a span of horses and some household furniture and a few dollars in money, with which I started for Nebraska to take a homestead under the new law. I arrived here in March with just \$5 left, took a claim, put up a log house, and went to work. I have 160 acres of splendid land which will make me a good farm, which only cost me \$13; and five years' residence on it secures me the title by paying \$2 more at the end of that time. I have got 10 acres of land broken up and a good garden started, and am greatly indebted for the latter to volumes 20 and 21, of the *Agriculturist*, which I bought on the way out where I stopped over night. I have read them thoroughly, and come to the conclusion that I cannot get along without the paper. I have no experience in farming, and when I want information on any point I refer to the paper and am almost sure to find it—consequently I send the dollar for the present year, which I got by working out by the day, and this is the very best investment I can make. I wish some thousands of the hard-worked clerks and mechanics in the city, that have families to support, could know what a chance there is here for them to secure a home and a sure competency. I have been through the mill, and can truly say that I am happier and better contented here in my log house, with the prospect before me of securing an attractive home for myself and children, than I ever was when in successful pursuit of a mercantile business. Here is ample room for thousands—produce of all kinds is high and commands cash at any time. The soil is a light loam with a slight intermixture of sand, the country is healthy, plenty of good water to be had by digging 10 to 12 feet, to say nothing of creeks. My claim is on the great military road from Omaha to the mines, upon which hundreds of teams pass dai-

ly, laden with stores of every description. The middle branch of the Pacific Road (when built) will pass near here, and right here in the valley of the Platte River are thousands of acres waiting for somebody to take them in possession—"to tickle with a hoe, that they may laugh a harvest." Do tell the poor hard-working drudges that barely eke out a scanty subsistence, that here they could be lords of the soil and soon gain an independence.

A Few More Humbugs.

Circulars and Advertisements of various swindling schemes continue to be received at the *Agriculturist* office, from subscribers who have been duly warned by our previous exposures, and are desirous of having others put on their guard. The following are among the latest new operations. A writer in the Chicago Tribune, in a long communication claims to have discovered an infallible method of determining between the middle of October and the middle of February of each year, what will be the success of the wheat crop of the following season. He professes to have tested his theory for thirteen years past, and found it infallible. He modestly claims to predict with certainty only concerning the "territory west of Lake Michigan, and north of forty one degrees, and to some extent South of that line, but would not be so sure, as the effects of those causes disappear as you go south." What becomes of the causes after the effects have disappeared, we are not informed. This individual proposes to impart this information for sixty dollars, or thirty dollars each year for two years, or ten dollars a year for ten years; at the end of that time the key of the guide will be given; but all necessary information will be given before the seeding time of each year, etc." He oracularly says "this year is indicated by those causes to be an extreme one—either very large, or very small. Immediately after seeding time I will state which." Seeding time is past, but we have not yet seen the promised statement. This man may sincerely believe he can do what he professes; we do not, and advise our readers to remain incredulous and save their money.

HEIRS WANTED FOR A LARGE ESTATE.—One of the easiest ways to procure money, is to inherit it, and probably few persons have not at some time dreamed, either awake or asleep, of a fortune left for their enjoyment by some unknown relative. Occasionally such cases have actually occurred, and being duly set forth in the newspapers, have added stimulus to the imaginations of fortune seekers. Sharpers have not left this field unworked, and their circulars glitter with golden hopes for those longing for easily obtained wealth. One professes to keep a register of all unclaimed property in England, to which register, access is allowed for one dollar. Another requests all families of a certain name, say Smith, to communicate with him concerning a large estate to which the Smith family are heirs; of course a small fee is expected if particulars of the said estate are required. In one instance the promised estate was said to have been lying unclaimed in England one hundred and fifty years. There would be about as much probability of heirs in this country realizing from such a property now, as there would of recovering Pharaoh's crown by fishing in the Red Sea. The circulars containing such offers are worth something as material for lamp-lighters, or making over into

new paper; to which use we commend them.

TRANSMUTATION.—Not of wheat into chess, but of copper and zinc into gold, or something that resembles it. A "Dr." sends out circulars from New-York City soliciting agents to sell the "British Metallic Mutual Association Transmutator's Guide." There's something in that name, surely. It is said to be the most complete exposition of ancient Alchemy ever published, "contains important information to bankers, merchants, farmers, mechanics, clerks, laborers—in fact the most important information to every one ever brought to light from the Hidden Storehouse of Nature, being a sure fortune to all who possess a copy of this work, and practise, as laid down in the simple receipts in the Guide." Then for the inevitable one dollar extra, "a person may become a member of the Society and enjoy all rights, benefits, &c." We can tell the reader how to make two dollars in connection with this concern. Just keep your money; it will be clear gain; the "transmutation" consists in transferring cash from the pockets of the credulous to those of a "sharp practitioner." If any choose to invest in the scheme, will they please inform us when they are successful; we desire to be present "when the laugh comes in,"

"American Farmer and Mechanic."

Perhaps an apology is due to our readers for not earlier denouncing this concern outright; we have hinted at it several times, but it was claimed by some that the more recent operators intended to fulfill their promises, and were only temporarily hindered by the "hardness of the times, etc." Two or three numbers were issued last year, with the suspicious claim of being "an old established Journal." Then came out a January number, with large promises of the future, and private circulars to Postmasters and others, offering great inducements. We could not say these promises would not be fulfilled. The reputed publisher could never be found when we called, or sent round, as we did frequently. Complaint after complaint continued to arrive, and we followed up the concern, with no satisfaction. To day (May 29) we went with one of the swindled Postmasters, determined to call to a prompt personal account whomsoever we might find in, be he clerk, boy or the "boss" himself. But the shop was shut up—occupied by another business—and to our inquiries through the building, the answers were, "gone down," "gone up," "gone off," etc.—When a responsible agricultural or horticultural paper, with a fair prospect of continuance, is next started hereabouts, we will announce the fact in the *Agriculturist*. Until then, better give a wide berth to these hundred and one new agricultural papers in New-York City, got up by parties who think it easier to make a fortune by gulling farmers, than by honest labor.

Treatment of Kicking Cows.

J. C. of Norfolk, Ct., says in a letter to the *Agriculturist*: "The following treatment, which I have tried for some years, has never failed to stop the evil. Put a strap around the body of the cow just in front of the bag and buckle rather tight. If the cow tries to kick, draw the strap a little tighter. She will never get used to it, and it never does any injury. She will keep on eating as usual, but has no inclination to lift her feet even to walk about." This may answer the purpose; the experiment is easily tried.

A COLLECTION OF AMERICAN FERNS.

Sketched and Engraved for the American Agriculturist.

Our Beautiful Native Plants—Ferns.

For grace and beauty of form, nothing can exceed the ferns of our woodlands. Every one who has walked in the woods with his eyes open, must have noticed these striking forms of vegetation. Some are found in the open fields and by the road-sides; others hang upon the face of the rocks, and others grow in the swamps; all are beautiful, but those of our damp and shaded woods are the most so. Their peculiar habit and graceful outline has made them favorites with the cultivator, and our green-houses frequently contain collections of foreign ferns, many of which are inferior in beauty and interest to our native ones. What can be a finer type of almost tropical luxuriance than the Ostrich Fern? What shows more beauty of finish than the Maiden-hair? What more graceful than the Climbing-fern, or more singular than the Adder's-tongue and the Walking-fern? Our artist has given a sketch which represents the general effect of a group made up of ferns. These differ from the great mass of our vegetation in many peculiarities. One of these is, that they produce no flowers or seeds, but grow from minute bodies, so small that they appear like dust, which are found in little cases; these grow in clusters or dots either upon the back of the leaves, or in a sort of cluster formed by a rolled up leaf. The engraving of the common Polypody (fig. 2) gives an idea of how these fruit dots appear, where they grow upon the back of the leaf, or *frond* as it is called. These are of different shapes, and are frequently covered by a sort of membrane. The separate spore cases are very curious. Fig. 3 represents one of the most common forms magnified. The

right hand figure shows an entire one: a little stalk bears a case which has an elastic ring extending part way around it. When mature, the elasticity of this ring breaks open the case, and the dust-like spores fall out, as shown in the left-hand figure (3). These are individually very minute, and can only be seen, when a larger number are together, and are so light that they may be borne about by the winds to a great distance. The Adder's-tongue and others bear their spore cases on a frond which is rolled up so as to make a sort of spike; this is very simple in the Adder's-tongue, but in others it is much branched and looks altogether different. We can not, in a popular article like this, give all of the peculiarities which characterize the ferns, but recommend our readers to the descriptions and figures given in Gray's Manual. With a little care, these beautiful plants may be made to adorn a shady corner of the garden. They require moisture and drainage, and grow well upon rock work in a sheltered and moist place. A bank of soil two or more feet

Fig. 2.

and grow well upon rock work in a sheltered and moist place. A bank of soil two or more feet

high, mixed with brick-rubbish and old mortar, is suited to the growth of most species, those which grow naturally in moist places being planted at the base of the bank, and others which like a drier soil, above. A mound of this kind covered with ferns will be one of the most attractive objects in the grounds. The damp loving kinds may be grown in a glazed case or under a glass shade, and make a beautiful ornament for the parlor. Some of the ferns of the green-house are beautifully variegated; the Golden and Silver-ferns add beauty of color to their elegance of form. The tree ferns, which are rarely seen in our hot-houses, found in South America, Van Diemen's Land, and other countries, are among the most beautiful and striking vegetable objects.

Fig. 3.

Rock Work.

One of the prettiest things in the lawn or garden is a nice bit of rock work, imitating, as nearly as possible, what we often see in a rocky dell in the forest. We often come upon these things in our rambles in the woods, quite equal to any thing in the Ramble in Central Park, and wish we could remove them, rocks, plants and all to our own premises. We stop in our walk to admire the ease of the natural grouping. The grace of the ferns, and the beauty of the flowers make us wonder they have never been transferred to the garden. Many of them have been, and from want of studying their habits

and wants, have died. Few plants accustomed to grow in the deep woods, and in moist places, will live when transplanted to an open border in the garden. The shock is too violent. But if put in the shade, and planted in a good border of vegetable mold from the forest, most of them will live and flourish.

A shelter of evergreens makes one of the best screens for rock work, but the shade of any tree, or the north side of a building will answer, if nothing better can be had. If a spring or fountain is on the grounds, the rock work should be located near it, so that it can receive copious waterings at pleasure. No definite rules can be given for constructing these ornaments. They should not be merely piles of loose stones, or regular in outline. The larger the rocks, the better for this purpose, and the more irregular the better. The spaces between, may be partly filled with stones, and with vegetable mold from the woods. A great variety of plants, will thrive in such a location. Many of the ferns and mosses, of which we have a large number, will do well. Only the larger ferns should be employed, where the work is on a large scale. In transplanting, the more earth we remove with the plants, the more likely they will be to live. The club mosses with their long trailing vines and bright green shoots, are highly ornamental. In selecting the plants it is desirable to secure a succession of blossoms, from the early Spring to late Autumn. The Blood Root, (*Sanguinaria Canadensis*) comes early in April. It loves moist, shady places, and is often found growing in the clefts of rocks. The Wood Anemone blooms about the same time, and is found in the same localities. The Saxifrage, and Rock Geranium, or Herh Robert, are also desirable plants. The Partridge Berry, and Winter Green, or Checkerberry are even more beautiful for their leaves and berries, than for their blossoms. The berries are of a bright red, and hang on through the Winter. The trailing Arbutus, one of our most beautiful flowers, the *Linnaea borealis*, Blue Houstonia, Columbine, and many others will flourish in rock work. Health, pleasure, and instruction will come of this home made ornament.

Gravel Walks on Hill Sides.

Here is one of the hardest things to manage in ornamental gardening. It is easy enough to make them, but to construct them so as not to gully and tear up in heavy rains, is not a little difficult. A few hints are offered: Such walks should, of course, have a solid foundation of stones, and this should be covered with gravel or shale. To enable the walk to shed rain, have it quite well rounded over in the center. The central parts should also be pounded or rolled so smooth and hard that running water can make no impression on it. If the walk is not long or very wide, the water accumulating upon it may be shed off upon the adjoining turf. But to secure this, the channel of the walk must be filled up brimful with gravel. Where the walk is long and wide, and the hill steep, this can not always be done, and provision must therefore be made for carrying off the water in gutters. These may be made of small cobble stones laid neat and smooth, or of bricks. If stones are used, they should not be larger than a goose-egg, and should be fitted in a workman-like manner. Provision should also be made for turn-outs at proper intervals, which may discharge the water upon the adjoining grass, or into cesspools, or under-ground drains.

In our own experience, we find the above methods to answer tolerably well, yet they are not a perfect protection in violent storms. At such times, the water will fill up and surge over all the gutters and turn-outs, and tear the walks sadly. The only way we know of is to provide these remedies as effectually as may be, and then lay in a stock of patience against storms.

Since writing the above, we have met with the following in one of Loudon's works: He is describing the grounds of an English country seat:—"One practice at Redleaf is, that in every part of the garden, where the slope is considerable, the walks are paved with brick, and have brick or stone-edgings. Some great advantages result from this practice. The walks are never injured by rain, but rather improved by being washed clean. No weeds grow in them; they do not become soft with rain, nor powdery in dry weather. Gravel walks need renovating, trimming and cleaning every year or two, but brick walks if properly laid at first, with a solid foundation and good drainage, will last ten or twelve years without any repair whatever."

Layering Grape Vines.

This operation is very simple. Early in the Summer, take down a last year's cane from the trellis, and after making a trench near the vine, five inches deep and a foot or two long, lay down the cane in it, and cover it up with fine soil. The layer should be fastened down by pegs or by stones. Bring up the extreme end of the cane and tie it to a stake. In the Fall, if all has gone well, the layer will have formed a large bunch of roots at the point buried, when it may be severed from the parent vine, and planted. Latterly it has been found that most varieties can be multiplied faster than by this method. The plan is to spade up and enrich the soil all along the side of the vine. Make drills not more than two inches deep, and as long as the branches to be layered. Sprinkle a little sand in these drills. Now, lay down the canes in these shallow drills and peg them fast at every joint. Tie up a foot of the end of each cane to a stake. Such sorts as Rebecca, Logan, Concord, etc., will soon take root at every eye, and will also send up shoots from the same joints. As these shoots grow, a little soil should be drawn over the layers, and the shoots tied up to stakes. By careful management in this way, one can get about as many rooted plants as there are buds on each layered branch.

Grafting the Grape.

"L," St. Louis Co., Mo., writes to the *Agriculturist*, that he "has been very successful in propagating grapes by grafting. Two years since I purchased a Rebecca vine, with a stem a little larger than a darning needle. I trimmed off the wood to two eyes, and although the buds were swelled, I grafted the part cut off on a piece of wild grape root, and planted it in the open air. In a year after it was, and is now much better than the original stock. The Delaware, Rebecca, and some others, with me grow better on other roots than on their own. My method is as follows: Make as much bark meet as is practicable. Where the root is larger than the cion, split the cion, sharpen the root, and cut out a deep gash or wedge in the centre of the root between the two sides, leaving the bark undisturbed. In inserting the cion, bend or press the sides of the root, until the bark of the cion and root meet, then wind with soft twine,

Furrow out the ground with a one horse plow, put fine chip manure about the plants, placing them about eight inches apart in the rows, and cover with common soil. Have the top of the grafts two or three inches above the level of the ground, and cover them out of sight one or two inches. If the season is unusually rainy and cold, place 6 inch boards on each side of the row, roof shape. When the weather is warm and settled, dig down to the buds, and leave them uncovered. If it continues very dry, cover the buds up, and let them find their way out."

Thinning the Leaves of Grapes.

One of the most absurd practices prevalent at this season of the year, is that of pulling off the foliage of grapes, in order (as it is said,) to ripen up the fruit. Those who do this say they can't bear to see the clusters so shaded: they *know* the sunshine would color them. And so they thrust right and left, covering the ground with green leaves. This is a great error. The ripening of fruit depends upon the presence and successful working of well-formed and healthy foliage on vigorous vines. The leaves are the lungs and stomach of the plant. Through them it breathes; by them it digests its food, and prepares nourishment for the fruit and the whole vine. Go to the sides of the forest, and you find the blackberry developing larger, and ripening up finer in partial shade than in the sunny field. Go a little further and you will find the wild grape growing luxuriantly and ripening perfectly where the sun seldom shines; certainly, where it never reaches the clusters, and where no one pulls off the leaves. Some of the handsomest clusters ever picked in our garden hung all Summer in the shade of leaves, and on the north side of the trellis-bar. The leaves had the sunlight all day, but the fruit did not. We have no doubt that one reason why the costly vine-ries of the country show so much half ripened fruit, is because the gardeners so perpetually meddle with the foliage.

Girdling Grape Vines.

This operation consists in taking out a ring or section of bark (say about an inch wide,) on the fruit-bearing canes. The effect of it is to enlarge the fruit above the girdle, and to give it the color of ripeness ten or more days before the usual time. It is an interesting experiment in vegetable physiology. It furnishes splendid specimens of fruit for horticultural exhibitions. But this is all we can say in its favor. The fruit itself is deteriorated for eating purposes, and clusters exhibited as fair specimens of the fruit, give an untrue idea of it.

Thin out Freely.

Two plants half developed are not worth as much as one which has had plenty of room to perfect itself. A much larger and finer crop of beets can be harvested if the plants are thinned to 8 or 12 inches, than if allowed to stand at 3 or 4 inches; and so with other crops—the distance of course varying for each. Not only will a larger yield be realized by thinning judiciously, but the quality of the product will be much better. So in the flower garden, the annuals are commonly sown very thickly, and left to crowd one another in a dense mass. For a few kinds this treatment will answer, but the majority will give greater pleasure if each individual has room to develop its beauty.

Summer Treatment of Fruit Trees.

Much of the work of the pruning knife can be anticipated by a little care during the growing season. Dwarf fruit trees, especially, can be kept in such a condition that they will rarely require much cutting. Buds tending to develop into superfluous branches may be removed altogether, and branches making too vigorous growth of wood may be shortened and induced to form fruit buds. If in the Spring we examine a shoot of a pear tree for instance, we shall find a strong terminal bud with lateral buds at intervals, and that those lateral buds are largest and best developed near the end of the shoot and that those lower down are gradually smaller. In the Spring the terminal bud starts to grow and prolong the stem; a few of the upper side buds produce shoots while the lower ones do not start at all. The buds near the extremities are the strongest and appropriate all the nourishment, while those below are starved. If in the Summer, while this shoot is forming, we pinch off the point of it, the supply of food which would have gone to continue its growth and form the strong upper buds, is directed elsewhere: the lower buds receive nourishment which they would not otherwise have had, and some of them will be likely to form fruit-buds. This pinching off the shoots to induce the formation of fruit-buds, is practised by all good cultivators upon their dwarf trees. They are thrown into bearing much earlier, and are made much more fruitful than when this is neglected. The time at which it is done will be determined by the season; whenever the shoot has made a growth of three to six inches, according to the vigor of the variety, it is pinched off by means of the thumb and finger, at the sixth leaf, counting from below. It often happens that a shoot stopped in this way, pushes again from the upper bud. In this case the second growth should be pinched back to three leaves. Summer pinching should be practised on young trees, to cause them to grow into proper shape. The upper branches of a young nursery tree, which has been cut back often, make such a vigorous growth as to overtop the leader: by pinching back these shoots, in time the tree may be brought into a proper conical shape. By timely pinching, the tree may not only be shaped at will, but be induced to bear fruit several years earlier than it otherwise would, and all cutting out of large branches be obviated.

Treatment of Orchards.

Many a farmer plants an orchard, and conceiving that he has done all that is required of him, takes no further trouble with it until, in the course of years, there is fruit which needs gathering. Perhaps by the time his trees come into bearing, he has been induced to take an agricultural journal, and there learns that trees are pruned to render them more productive. Pleased with the little fruit he already has, he admits the necessity for pruning, and goes forth with knife, saw, and axe, and makes an indiscriminate cutting, and thinks he has pruned his orchard. Next year the trees bear less than the year before and he sets down all pruning as useless, and all agricultural publications as humbugs. It is for the benefit of just such people that this article is written—those who catch at a fragment and think they have the whole. To all who this season begin to give attention to their orchards we say: Never cut a limb unless you see clearly that something is to be

gained by the operation. Look carefully at the tree and decide whether it will be better for any cutting, or if left alone. Do not cut unless the tree will be the better for it. If a limb grows in the center of the tree, where the fruit can not receive the influence of the sun and air, cut it out. If two limbs cross one another so that both will be chafed by the action of the wind, cut off one of them. Does a limb grow in such a direction that the tree will be thrown out of balance and grow lop-sided—off with it. Unless a limb is evidently useless or in some way injurious, it need not be removed. There are two extremes: one is to let the tree grow without any care, and the other is excessive and injudicious pruning—both are to be avoided. If the tree is doing well, let it alone; if disposed to make a too rampant growth of wood, more than can be thoroughly ripened, cut it back; but as a general rule be sparing of the pruning tools. If an orchard has been properly cared for *from the beginning*, the amount of annual pruning required will be very small; no tree ought to get so far out of bounds as to require anything more than the knife. Still there are many who have neglected their orchards, or who come into possession of old and neglected ones, where a severe pruning must be practised. This is the proper month in which to do it. The trees are now in full vigor, and an attempt will be made to heal over any wound made in pruning. If the limb to be removed is large, use a saw, set rather wide, and be careful that the limb in falling does not tear off a portion of the bark and leave a ragged wound. To prevent this, it is well to make an incision with the knife, quite through the bark at the place where the limb is to be sawed off. Do not leave long stubs, but saw close to the base of the limb. It is advantageous to cover the wound with a solution of shellac in alcohol; this may be made of the consistence of paste, and applied to the wound by means of a brush. In going over the orchard, remove all suckers and all those sucker-like limbs which in old trees are apt to spring from the larger branches. Apple trees will, where the Winter is severe, be benefitted by a summer pinching of the vigorous shoots; see article on summer pinching, on the opposite column.

Introduction of Fruit to England.

A book of the olden time published in London, in 1604, gives the following account of the improvement of the stock of fruit in England.

"One Richard Harris, of London, borne in Ireland, Fruiterer to King Henry the eight, fetched out of Fraunce great store of grafts, especially pippins: before which time there was no right pippins in England. He fetched also, out of the Lowe Countries, Cherrie grafts, & Peare grafts, of diuers sorts: Then tooke a peece of ground belonging to the King, in the parrish of Tenham in Kent, being about the quantitie of seauen score acres; whereof he made an Orchard, planting therein all those foraigne grafts. Which Orchard is, and hath been from time to time, the chiefe Mother of all other orchards for those kindes of fruites in Kent, and of diuers other places. And afore that these said grafts were fetched out of Fraunce and the Lowe Countries, although that there was some store of fruit in England, yet there wanted both rare fruit, and lasting fine fruit. The Dutch & French, finding it to be so scarce, especially in these countries neere London, commonly plyed Billings-gate, & diuers other places with such kinde of fruit. But now

(thanks bee to God) diuers Gentlemen and others, taking delight in grafting (being a matter so necessary and beneficial in a Comon-wealth) haue planted many Orchards; fetching their grafts out of that Orchard, which Harris planted called the New-garden. And by reason of the great increase that now is growing in diuers parts of this Land, of such fine & seruiceable fruit, there is no need of any foraigne fruit, but we are able to serue (serue) other places."

Labels on Fruit Trees.

No one who has many fruit trees, should trust to labels for their identification, as they are liable to be defaced or lost altogether. Make a plan of the orchard or fruit garden, and mark the place of each tree, writing down its name. This, if kept where it can be readily referred to, will save a deal of trouble in ascertaining names when the tree comes into bearing. Our special object is to call attention to the trees planted this year. When the trees are labeled in the nursery, the wire by which the tag is attached, is usually bound closely around a limb or the body of the tree. If it was not loosened at the time of planting, it is probable that the growth of the tree has caused the wire to become so tight as to seriously interfere with the health of the tree. We have frequently seen young trees with the copper wire of the label completely imbedded in the bark. The trees should be looked over to see that no injury results from this cause. Where very small wire is used, the expansion of the tree breaks it and the label is lost. Use rather large wire and give plenty of room for growth. Lead wire is preferable to copper; it is very cheap, and will yield to the enlarging growth of the limb.

Summer Pruning of Hedges.

After hedges have reached nearly their intended height, it is necessary to prune them in mid-summer, in order to check their too vigorous growth. Yet this should be done with care. Too harsh use of the shears at this time stunts and often kills plants. Nature must have an outlet somewhere, and if forbidden, she rebels. And then, both as a matter of taste and expediency, it is unwise to give the hedge an absolutely smooth shearing. Better is it to leave some freedom and flow in the outline of plants, than to crop them very close. Better to clip in here and there, checking the strong growths for one year, and leaving the weak a chance to extend themselves a little. This will give the hedges something of the wavy outline of a symmetrical shrub, rather than the stiff appearance of a primly shorn wall. And, not least important, such a hedge will last much longer than one which has been too closely pruned.

The Chinese Wistaria.

To the lovers of flowers our city streets do not present many attractions, yet in the month of May we have walked through many streets to enjoy the Wistaria. It seems to be the favorite climber of the New-York people. It climbs along walls, hangs over balconies, mounts to the roofs, and sometimes to the very chimneys and hangs its great grape-like clusters everywhere. The plant often improperly called *Wisteria* and *Glycine* is named in honor of Dr. Caspar Wistar, a late celebrated physician of Philadelphia. A native species is found in Penn-

sylvania and southward, but it is much inferior in beauty to the Chinese species, so generally cultivated, (*Wistaria Sinensis*). The plant is readily propagated by layers and by cuttings, and is a universal favorite. It is perfectly hardy in the climate of New-York, and would succeed, by laying down in Winter, in much less favorable localities.

A Strawberry Talk.

At the Fruit Growers' Meeting held at the office of the *Agriculturist* on June 5, the merits of the different varieties of strawberries were discussed. The meeting had an especial interest on account of the presence of Mr. J. Knox, of Pa., one of the largest, if not the largest, cultivators of strawberries in the country. Mr. Knox thought there were several varieties of strawberries, possessing great merit, which had been overlooked. He instanced the Fillmore as one of these. He considered it one of the best in his locality, but was well aware that the locality had much to do with the value of a variety. While Hovey's Seedling was highly prized at Boston, it was almost worthless at Pittsburgh. The Fillmore does not need to be frequently renewed, while Wilson's Albany does. The Wilson gives a few large berries at first, but the rest of them are small. The Fillmore gives a greater crop than the Wilson and is of better flavor. He has tested it thoroughly and has this year planted more of it than of any other variety, save Triomphe de Gand. He named as other good sorts: Golden Seedling, Comtesse de Thury and Duc de Brabant. The Triomphe de Gand fully sustains its reputation; taken all in all, we have nothing equal to it. Being asked to give a selection of the best six strawberries, Mr. Knox placed 1st, Triomphe de Gand, medium and late; 2d, Wilson, as desirable for canning or bottling; 3d, Fillmore; 4th, Baltimore Scarlet, early; 5th, Burr's New Pine, one of the best; 6th, Jenny Lind. The strawberry season used to extend over only two or three weeks. At Pittsburgh, they had prolonged it to seven weeks, and he had no doubt that it might be extended to two months. Trollope's Victoria does not bear carriage well, but it is good for home consumption. Kitley's Goliath is very large and late, but rather coarse. Brighton Pine has been said by the Pomological Society to be a poor bearer. Mr. Knox considers it one of his best bearers, and it has a fine spicy flavor. Scott's Seedling is very good; some parties prefer it to all others. There is a great variety of tastes to be consulted, and a cultivator must endeavor to suit all. The Moyamensing is good. We do not want merely good sorts, we want the best. A first rate variety takes no more room and costs no more labor in cultivation than a poor one. Mr. Knox intends to plant ten acres of strawberries each year. They are as easy to plant as cabbages.

Doct. I. M. Ward thought that many kinds would succeed well about Pittsburgh, which would not do well in other places. Hovey's Seedling is one of the best in the vicinity of Newark, N. J.

Mr. W. S. Carpenter objected to the Fillmore as it is a pistillate variety. Is testing Cutter's Seedling, and is thus far pleased with it. Among the new foreign varieties the Prince of Wales is a wonderful bearer and good. The Duc de Brabant is a favorite with him. He has tried some of Mr. Fuller's Seedlings for two years, away from the locality where they originated. He thought highly of Col.

Ellsworth. The Brooklyn Scarlet is a splendid berry, being perfectly hardy and very productive, though the berry is not as large as some. Some white berries were of great promise: Lenning's White is perfectly hardy, of large size and good flavor: the White Pine Apple is nearly as good. Jenny Lind is a favorite at the North, being large and of a fine color: Iowa is too sour. Downer's is a wonderful bearer, but too sour. Bartlett is very fine, about as good as the Fillmore, and having perfect flowers, he prefers it to that variety. Empress Eugenie is one of the best, as good as Burr's New Pine. Princess Frederick William was loaded with fruit, early and fine. Scott's Seedling, not productive, insipid but sweet.

Dr. Ward stated that the Brighton Pine was not prolific with him, and had rooted it out on this account. Mr. Knox thought he could not have the true sort as it was a great bearer with him. Solon Robinson had thrown it out, it not being a good bearer.

Mr. Knox said that he never endorsed a strawberry until he had proved it by cultivating it for three years. He looked for progress and thought that perfection had not yet been attained. He might put one variety at the head at this meeting, and at another meeting would consider some other variety as superior. His views were constantly changing as he had more experience, and varied his modes of culture. When a bed begins to run out, after gathering the fruit, he lets the plants make all the runners they will. He then plows them under, adding stable manure, and puts strawberries on the same ground again. He considers a crop of strawberry plants equal in value to one of clover to plow under.

Dr. Ward stated that Mr. Winans had tried every variety known in this vicinity, at Newark, N. J., and had found the Boston Pine and Hovey's Seedling the most profitable sorts.

Mr. Knox thought that the best culture had not been reached in this vicinity, as he could send his berries here from a distance of 300 miles and sell them at 50 cents a quart at wholesale, and asked if we had the best kinds for this locality. Cutter's seedling he considered a fine berry, but not large enough, it is light colored and too soft to bear carriage to market.

Saving Seeds in the Garden.

Our cultivated plants seem to be in a condition of unstable equilibrium: on the one hand they tend to deteriorate, and on the other certain individuals seem disposed to attain to a higher degree of perfection. We do not, as a general thing, understand the causes which produce these results, except that for the most part poor culture produces the former, and good culture the latter effect. Most of our finest varieties of vegetables and flowers have been produced by a judicious selection, and if we would keep any variety in perfection, we must continue to select the best specimens to propagate from. "Like produces like," is a rule sufficiently general to be followed, and high breeding may be practised with plants as well as with animals. If we sow a large quantity of seeds of any variety of plant, a difference, and often a very marked one, will be noticed in the seedlings; such as vigor, early maturity, and superiority of product. In garden culture we pay too little attention to the saving of seeds; hence it is that we hear complaints of sorts running out, and the necessity for a frequent change of seed. It has been our custom, though often

against our inclination, to save the earliest and finest of our cucumbers, melons, tomatoes, etc., for seed. Those who wish to keep their varieties good and even to improve them, will do well to follow this practice. Selection of the most desirable sorts for propagation is the great secret in producing the many improved kinds of vegetables. The variations are produced by hidden causes, and it is left for us to take advantage of them. Both in the vegetable and flower garden, let the seed be saved from those plants which present the most desirable peculiarities, and the chances will be that their good qualities will be perpetuated in the progeny.

Use the Kitchen Slops.

Just now the English agricultural papers are full of articles upon the use of sewage or waste of cities. Bringing this subject down to individuals, we might write a long article on the waste of the house, had not this subject been so frequently presented in the columns of the *Agriculturist*. Again we say allow no fertilizing material to go to waste. The water from the kitchen is rich in elements of fertility. The soap used in washing, pot liquor, salt, etc., are all needed by the garden, and will amply repay for the saving and applying to the plants. On many farms the sink spout discharges into a gutter, and the waste water is allowed to soak away or evaporate, and just along the edges of this gutter will be found a most luxuriant growth of weeds, showing plainly that the ground here is richer than elsewhere. Let the kitchen waste be collected in a sunken hogshead or cistern, and applied in a liquid form to the plants in the garden, or run it to a convenient distance from the house to an excavation which can be readily supplied with muck, which will absorb the liquid, and many dollars' worth of manure now wasted, will be annually saved.

Training Dahlias.

This most showy flower, the chief ornament of the garden during the early Autumn, requires constant care, unless we would have our hopes end in disappointment. Throwing up a vigorous and tender stem, its branches have so little strength that they often break with their own weight, and if not kept securely tied to a stake the main stem will be prostrated by strong winds. For all except the very dwarf kinds, stakes are needed, and some mode of training must be adopted. One method is, to tie the main stalk to a stake and take off the lower branches, to prevent their breaking off of themselves. This causes the plant to grow very tall, and gives but a comparatively small number of flowers. Another style, called the "tub" method, is to cut off the leading stem and allow four or more of the lower branches to grow, each of which is furnished with a stake. This plan secures a large number of flowers, but gives the plant a squat appearance not in accordance with its natural habit. We have satisfactorily practised a method which combines these two methods of training. The main stalk is supported by a stake in the usual way, and all of the side shoots, except the three lowest ones are kept carefully pinched off; as soon as these lower shoots acquire a sufficient length they are supported by light stakes inclining outward from the plant. Trained in this way the Dahlia in flower presents a most showy appearance. Hoe around the plants frequently, apply liquid manure, and if a dry spell occurs, cover

the ground with some kind of mulch. Much of the success in flowering the Dahlia, depends upon careful tying. Every few days the new growth should be secured to the stakes by a tie of bass bark or a strip of cotton cloth. Care should be taken that the bands are not drawn so tightly as to impede free growth.

A Fine Old Plant.

Plants as well as other things are subject to the changes of fashion. Many of the old favorites of the gardens are neglected merely because they are old, and their places are occupied by others whose chief merit is their novelty. For ourselves, we love to see the flowers which we knew when a boy: they seem to us as old friends. How many of us look back with pleasure to days spent in the garden of our early home. Its treasures may have been only Sweet Williams, Pinks, Pæonies, and such old-fashioned flowers, but they are dearer to us than any of the newer introductions, for they bring pleasant memories of the days of our youth. Such were our thoughts on receiving a bunch of Thrift, from Mr. A. S. Fuller of the Brooklyn Nurseries. He sent it to us, knowing our partiality for old plants, and we have had it engraved, believing that it will be a novelty to most of our readers. The plant is botanically *Armeria vulgaris*. It is a native of Europe, and a perfectly hardy perennial. The leaves make a dense mass of dull green foliage, against which the abundant pink or rose-colored flowers make a fine show. It is well worth cultivating as a bedding plant, but it is particularly valuable for edgings, for which it is much used in England, where it is considered as the next best plant to Box for this purpose. It is readily propagated by division of the roots. There is a white variety.

About Double Flowers.

Every cultivator of flowers has doubtless experienced a difficulty in reproducing double annuals from the seed. The double flowers are in an unnatural condition, and it seems that slight causes induce them to revert to their natural state of single ones. There is much relating to this subject that we do not understand. There are some plants, like the stock gilliflower for instance, the double flowers of which do not produce seeds, but the single flowers have a tendency to produce seeds, the majority

of which give double flowers. In a "good strain" of stocks, as the gardeners term it, the tendency is to produce double flowers, with here and there a single one to continue the kind. The whole thing seems to be in a very precarious condition, which slight and little known causes will modify. Seed saved from the most double Zinnias, will give us a number of single flowers, while the China Aster, which seems to have its double character more fixed, rarely fails to produce double ones. We have before us two letters upon this subject. The first is from Carl Meinurth, of Rockingham Co., N. H., who commenting on the statement made at the bottom of the last column, on page 148 of May *Agriculturist* says: "Seeds from double flowers, which are not constant in reproducing double flowers again, must not be sown before they are one or two years old." To test his theory he suggests that we take a paper of seeds of any double flowers, and sow one half the seeds this year; perhaps one-tenth of the plants will be double and the other single. Next year sow one half of the remaining seeds, and one half of the plants, at least, will be double; finally, the third year sow the rest of the seed and quite probably all the plants will bloom double. He also suggests that the smallest seeds of the Balsam are more likely to produce plants with double flowers, than the full plump seeds.

Another correspondent, "G." gives his plan for procuring seeds that will produce double flowers thus: "Do not allow the plant producing seeds to mature all of them. Pick off one half of the flowers, and let the plant throw all its forces into the remainder. Give the plant itself every possible chance to make a vigorous growth before it forms its flower-buds. An annual flower, like the Aster, is more likely to give double flowers and seeds, if transplanted from a seed-bed, than if grown in the border where they were first sown."

Rake the Garden.

"L. G.," writes to the *Agriculturist*: "My garden is a light sandy loam. When it is spaded in the Spring and raked over, it is perfectly smooth and level. After planting I, like a certain kind of bird, cover up my tracks. As soon as the vegetables begin to appear, I rake over the ground—going backwards, meanwhile, "crab-fashion," leaving no tracks visible—so that many have said to me, "How is it you keep your garden so clean and smooth? If the garden is raked over weekly—not a weed can be seen, the ground is kept from drying up, in fact the loose surface, though perfectly dry, operates as a mulch. To one unaccustomed to this mode of gardening, it is perfectly surprising how much ground can be gone over, and effectually too, in a short time. Wrought iron rakes are better than steel, as the teeth do not suffer from rough usage. I have not taken a hoe into my garden for the last 15 years, as I can make "better time" with the rake, even among corn and potatoes. Certainly in beds of onions, etc., there is nothing equal to the rake; if the rows are not far enough apart for the rake, turn it a little sidewise. Whoever will try the above plan, I think "will irresistibly come to the conclusion" that, running over the garden with a rake (if the soil is light,) once a week, is true economy—much better than to wait till weeds can be seen. Very slight motion of the soil destroys the roots of weeds while they are so tender. While you can not see such a victory at this time as you could if the weeds were knee high,

still it can be enjoyed full as much as though one could see "the slain lie heaps on heaps."

The Striped Bug a Night-Worker.

C. G. Siewers, of Campbell Co., Ohio, in a letter to the *Agriculturist* says: "I never could see how the few striped bugs found in the morning, could do the damage my squash, cucumber, and melon vines were daily suffering. One night last year, I lighted my lantern, and went to examine my vines. Let any subscriber afflicted as I was, do the same.—I found my vines covered with bugs, 50 pair on a leaf being nothing uncommon. With finger and thumb I slaughtered about a thousand in an hour, going over the vines twice; about 12 o'clock at night I visited them again, and found but a few stragglers. Next night I went once more, in the hope of seeing no more bugs, but found that there was no apparent diminution of the enemy. I slaughtered them wholesale every night for two weeks, and then gave up in despair. In an adjoining patch I had a fine lot of late cucumbers coming along—very thrifty, and untouched by the bug, and without thinking of the consequences, I tore up all my squash plants, finding they would never set any fruit, and threw them into the manure heap. The next morning my entire cucumber patch lay wilted and destroyed, looking as if a heavy frost had cut them down; every leaf appeared chewed up. I have not planted any this year."

The Asparagus Beetle.

This insect, which has caused such destruction in Europe, has already become established in some localities in Long Island and New-Jersey, where it promises, if its ravages are not checked, to ultimately destroy the asparagus crop. Fortunately the insect is thus far confined to a few localities. As it can only be exterminated upon its first appearance, we give figures of it in its several stages, in order that it may be at once recognized and promptly dealt with. The beetle is known to entomologists as *Crioceris asparagi*, and has a general resemblance to the striped bug which infests cucumber and melon vines. Fig. 1 is a drawing of the perfect insect magnified, which makes its appearance during the month

of May. A line near the figure shows the natural size of the beetle. The eggs are little brown oval bodies, singularly attached in rows upon the slender twig of the plant. Fig. 3, shows the eggs, both of the natural size and enlarged. The eggs shortly hatch and produce grubs or larvae which greedily devour the asparagus shoots.

Upon the first appearance of this dangerous enemy, no pains should be spared to exterminate it. The beetle should be picked by hand and destroyed, and all twigs upon which eggs are deposited should be burned. A brood of young chickens will be of great aid in destroying these and other insects. The hen should be confined in a coop and the chickens allowed to range over the bed.

THE HOUSEHOLD.

Vegetables for our Soldiers.

Perhaps there is no deprivation incident to a soldier's life, greater than being obliged to do without the ordinary vegetables. To be able to appreciate the value of potatoes, turnips, etc., one should be obliged to go without them for a few months. We have been where oranges, bananas, figs, and other tropical fruits were abundant and ridiculously cheap, and would have given them all for a good mess of potatoes. From their bulk and weight it would be impossible to supply a large army with fresh vegetables; but our government does the next best thing, it furnishes an occasional issue of carefully dried vegetables. Col. Eaton, the Commissary at this post, sends to the army one hundred and thirty five thousand pounds a month, of a mixture of dried or dessicated vegetables. We were much interested in a visit to the works of the American Dessicating Company at Brooklyn, L. I. This company furnishes the largest share of that supplied to the soldiers of our army, and has ample machinery and facilities for its operations. The compound sent to the army, consists, in every 100 lbs. of

20 lbs. dried Potatoes.	22 lbs. dried Turnips.
22 lbs. dried Carrots.	10 lbs. dried Cabbage.
10 lbs. dried Onions.	5 lbs. dried Tomatoes.
5 lbs. dried String Beans.	1 lb. dried Parsley.
5 lbs. Rice.	Pepper, etc.

This mixture is packed in cakes of seven lbs. each. It is an excellent article for a vegetable soup, or will make a nice dish of mixed vegetables. The drying is performed by exposing the sliced vegetable upon trays in chambers heated by means of steam pipes. A bushel of potatoes is thus reduced to 10 lbs., and other vegetables, containing a larger amount of water, weigh still less in the dried state. We were particularly impressed with the neatness which was observed in the establishment—much of the work being performed by women. The company has a separate contract for their dessicated potato, of which a large quantity is sent to the army. The potatoes are first cooked, and then granulated and thoroughly dried. They form an excellent article of food, and must be exceedingly welcome in camp. Mixed with sufficient boiling water, a nice dish of mashed potatoes can be prepared in a few minutes.

Drying Fruit and Vegetables.

There will soon be an abundance of the products of the garden and field, a share of which may be dried for Winter use. Now when there is an unusual demand for such things for the use of our brave soldiers in the hospitals, our patriotic women will prepare an increased quantity of these delicacies for the sick and convalescent. Persons connected with the Sanitary Commission inform us that there is no limit to the demand for dried berries, apples, peaches, and other fruits, and dried sweet corn and other vegetables are always acceptable. Where the quantity to be dried is small, it may be done on pans or trays placed in the sun and occasionally put into the stove oven, the doors being open. It is considerable trouble to put out the vessels when the sun shines, and bring them in at night, or on the approach of a shower. Where there are hot-beds, this labor can be saved by using a hot-bed frame and sash. The articles to be dried can be covered with the sash at night, which can be wholly or partly removed during the day. Where a large quantity is to be dried, it will be better to depend entirely upon fire heat. We have used successfully a very simple contrivance, a common wood stove, with the pipe running across the room about two feet from the floor. About a foot above the pipe a rack holds the trays upon which the article to be dried are spread very thinly. The stove being an "air-tight," a very little wood serves to keep the room at a high temperature. The trays most recently filled are placed nearest the stove,

and gradually moved along as the drying progresses, to be succeeded by others. Ventilation is to be secured by letting down the upper sash of a window. The fruit or other material should be spread very thinly at first, and the early stage of the drying should be pushed as rapidly as possible, to prevent souring. When partly dry, the contents of two or more trays may be united, and thus save room. When the fruit, etc., is nearly dry, it absorbs moisture rapidly, and should not be exposed during damp weather. Pack on a dry day. *

An Old-Fashioned Musical Instrument.

The above engraving will not be without interest to many readers of the *Agriculturist*. In thousands of minds it will awaken memories of early days, when the pleasant hum of the wheel was heard in almost every farmer's dwelling, when few young ladies thought themselves fit candidates for matrimony before a bountiful stock of homespun linen had been provided by their own industry for furnishing bed and board. "Ah! those were the days of healthy women, good housekeepers, and happy homes," exclaim those who remember only the golden hours of the past. "In those times, the music was worth something. Its notes brought money to the pocket, as well as pleasure to the ears; piano playing and spinning street yarn furnish but poor substitutes for the useful work that employed our grandmothers." It is no doubt very pleasant to look upon the past, mellowed by the light of years until a poetical tinge covers the picture, but the present is more than a realization of the dreams with which many a weary maiden beguiled the hours of toil imposed by the necessity of providing clothing entirely by hand labor, in addition to the other household duties. The ingenuity of man has disenthralled woman from a large measure of drudgery, and given her the opportunity to become something more than a mere working machine. It is doubtless true that many misimprove the leisure bestowed by the progress of manufactures, but this need not be, nor do we believe that, as a whole, the female sex have deteriorated either morally or physically, since their labors have been lightened by the introduction of machinery. It is certain that the average standard of female education is higher than ever before, and reliable tables of mortality prove that the duration of human life has been lengthened several years during the last century. That is a low view of life which regards as its object only the accumulation of outward possessions. True wealth consists in development of the faculties of the soul, in an eye edu-

cated to appreciate beauty, an ear to enjoy harmony, a refined taste to derive pleasure from art, as well as an intellect to grasp truth, and a hand to achieve onward results. He is not wealthiest who possesses most of this world's goods, but he who knows how to extract most enjoyment from his surroundings; and the resources of happiness are abundant to the cultivated and refined. The common people of the present day are far richer than the nobles of old, for general culture now is superior to what was then thought to be high accomplishment. And more than this, by means of im-

proved methods of manufacture, the day laborer is now better housed, clad, and fed, than were many princes of old.—The days of old and their appliances are not to be despised. They bequeathed much of strength and of excellence, but they were only the root and the leaf which were to nourish the flower of the present. A return to them would be like the cutting of an immature plant, forcing it to repeat the slow labor of preparation for seed bearing, the end of its existence. A striking illustration of this truth is furnished by events now transpiring. One of the "relics of barbarism" a state of society deeply rooted in past ages, and which like a pestiferous weed, yet remained amid surrounding culture, has borne its legitimate fruits, and we are in the midst of a desolating war, itself almost a type of the olden time, when might made right. The fruits of peace are being rapidly destroyed. At the South, the hand spinning wheel, and loom are again furnishing "homespun," and it may yet be necessary for Northern women to revive this almost obsolete art. Thank God, they are not incapable of the task when it shall be necessary, yet who will say that this would be a national benefit?—For many reasons we

revert to the past with pleasure, but never with longing eyes. We remember that the higher glory of the race lies ever forward, and rejoice that so many steps have been taken toward its attainment.

Tim Bunker on Keeping a Wife Comfortable.

"How long have we got to wait for dinner, I should like to know?" said Jake Frink to his wife Polly, one day in hoeing time. "Its tu bad to keep three men waitin' an hour for their grub."

"You've got to wait till the brush is cooked, with which to cook your dinner," said Aunt Polly snappishly. "None but a green-horn would furnish green-wood for his wife to cook with—and green brush at that. You know, Jake Frink, that you have never had a second cord of wood at your door any time since I have lived with you, and that is going on seven and thirty years. All that time green brush has been the chief article of kindling. One might think that your whole farm was a brush pasture teetotally. I should like to have you try cooking with green wood a little while, and see how you would like it."

"Wall Polly, hurry up any way," said Jake, "for we are all mighty hungry, and the corn want's hoeing badly. You see brush is economical, and what I can't sell at the store, I can use at home. It would kind o' rot on the ground ef I didnt burn it up."

"Pretty economy it is, to keep your wife in a stew all the while, and hired men a waiting hours every day because green wood won't burn. It is smoke, siss, and fizzle from morning to night, and I no sooner get a blaze agoing, than I have to put ou more green wood, and then there is another sputter. I never see such a house as this is," said Aunt Polly, with great emphasis, and with a face as red as a beet.

Jake is a great sinner, although he thinks he is so good that he does not need to go to meeting and hear Mr. Spooner preach. He would try the

temper of a much more saintly woman than Aunt Polly, and keep her on the rack. He might just as well put red pepper in her eyes, as to keep her kitchen always smoked up with green-brush. Her eyes always look red, and it is nothing under the sun but that smoky kitchen. The draft of the chimney is none of the best, but that would be remedied with well seasoned wood. Now you see that man had christian marriage, but he don't care no more for his wife than for a dumb animal. I guess he would lift a sheep out of the ditch, especially in these times, when wool is a dollar a pound. But he keeps his wife in the ditch about all the while, and never suspects that she is a bit uncomfortable. He thiinks he saves something by burning brush, but it don't pay unless you have a machine to chop it up fine, and keep it under cover until it gets dry. To work it up with the axe into fuel for a stove, it costs more than it is worth. If it lies on the ground in the woods, it rots and makes good manure without any expense. Then if you have it, or any other wood green, there is a matter of uncertainty about meals, which throws the whole work of the farm into confusion, and puts every body out of humor.

But this is only one way in which a wife is kept uncomfortable. It does seem as if some men took less care of their wives than of the dumb cattle in their fields. If the rooms in their houses had been thrown together by chance, they could not have been more inconvenient. A good arrangement of the rooms saves one half the labor. Some times the sleeping room is on the second floor, and there is many a journey up and down stairs during the day for a woman already overburdened with care. Sometimes the store room is in the garret, and other journeys have to be made daily, for supplies for the table. Every thing that she needs for her work should be upon the first floor, and close at hand. There is no unnecessary waste of strength then in filling her place as housekeeper, cook, dairy maid, laundress, wife and mother, for many a farmer's wife is expected to fill all these offices, and to be always cheerful and happy, waiting for the coming of her liege lord, as if she had nothing else to do but to be a wife.

The lot of a farmer's wife, as it generally runs, is rather a hard one, and is made hard very often from the want of attention to little things. If a man needs twenty cords of wood for the year, it costs no more to get it in the Winter, in a time of leisure, and to have it chopped, split and packed under cover, than to get it, a load at a time, and have the torment of a slow fire all the while. This not only makes more labor, but it frets and worries, which is a good deal worse than work. Dry wood is one of the secrets of a comfortable wife. That is what makes Mrs. Bunker so hale and handsome, past sixty. She says she wouldn't know how to keep house without dry wood. I guess she wouldn't for she has never had any thing else.

Deacon Smith is a good man, and means well, but he does not know how to use a wife. His well has hard water, that won't wash, and all the water on washing day has to be brought from the brook, more than forty rods from the house. To be sure he keeps a servant, but it makes a world of work for servant and housekeeper. He might have a cistern that wouldn't cost twenty dollars, and it would save more than that value of labor every year. He has roofing enough to keep it supplied with water all the while. And then the Deacon carries on a large farm and keeps a half dozen hired men, and boards and lodges them all in his own house. Now what a burden this brings upon a woman, when they might be much better accommodated in small farm houses of their own. It is quite as easy to hire a part of the labor needed on the farm, from those married, as from those who have no homes of their own. This leaves a farmer's wife with no family but her own to attend to, which is much more pleasant.

Then I guess a man has to do something to himself as well as to his house, to make every thing go smooth with his wife. She bargained for a man when she got married, and she has a right to be disappointed, if she finds she has nothing but a

working animal always jaded and unfit for social life. I know of some farmers who rarely go any where but to meeting and to market. They feel that they can not afford the time to dress up and go and see their friends and dine, or take a cup of tea. They have so slid out of society that their friends rarely come to see them. They are so hurried with work that they do not make friends very welcome. They seem to have no appreciation of life, but as an opportunity to make money. They prize work for this end, and time that isn't turned into money is lost to them. Their muscles not only become hard, but their hearts grow hard and unsympathizing. They lose their taste for reading, if they ever had it, and very soon fall asleep if they attempt to read, or hear reading. If they are active in the field, they are stupid and dull in the house, like tired animals in their stalls. There is no mental growth, no development of manhood in their lives. This discovery, I think makes a woman more uncomfortable than green wood, and smoky fires. She married a man—a creature of intelligence and affections—and she has the right to the companionship of a man while she remains a faithful wife. No man has a right to prostitute himself to mere money getting, no matter how honestly, or to turn all the energies of his being to menial exertion. Manhood is the most precious product of his farm, and whatever else suffers, that ought to be kept strong and vigorous. That article has become mighty scarce on Jake Frink's premises, and it is this fact that makes the green-wood so very green, and the smoke so trying to Aunt Polly's eyes. Poor woman! I shouldn't wonder if there was something else in them besides smoke sometimes.

Hookertown,
June 6th, 1863.

Yours to command,
TIMOTHY BUNKER Esq.

For the American Agriculturist.

Bargain-Hunting Poor Economy.

"See what a splendid bargain I made yesterday," said one of my neighbors who was exhibiting her purchases during a recent shopping expedition. "Only two shillings a yard, and they asked two and six at every other store." "But Mrs. W., I thought you had previously bought a Summer dress for your daughter," I mildly suggested. "Yes," was the reply, "she was fitted up; and it cost not a little to do it, I can tell you; but then this was so cheap, I could not bear to leave it. It will come good next Summer." "And very likely be so out of the fashion, that the daughter will not be willing to wear it," thought I, but politeness forbade me to say it. "And here is another real bargain," continued Mrs. W., "I never can get my husband to look out for the boys, and so I have to buy even their boots and shoes. Those boots I got for two dollars, when they were asking two and-a-half every where else." One look at the articles was enough to show even to my unpractised eye, that they were made of a poor quality of split leather, cheap indeed in price, but costly enough in every other respect. The first walk through a wet pasture would soak them like a sponge.

Mrs. W. had committed the two errors which "bargain hunters" usually fall into, and against which I would warn those of that class who may read the *American Agriculturist*. First, she bought what was not needed, because it could be had cheap. The fabric was apparently worth more than the price paid for it, but the money laid out might all have been saved for that season at least, and thus it was really so much out of pocket. Mrs. W. could not be sure that the same goods might not be purchased at a great reduction the following Summer. Fashions change rapidly, often in a single season, and they largely control prices. In any case Franklin's old rule holds good; "What is not wanted, is dear at any price."

The second error of Mrs. W. was in supposing an article cheap, because it was sold at a low price. Occasionally through stress of times, or by dishonest dealing, goods are sold at less than their value. In the first instance it is not according to the highest morality to take advantage of the necessities of

another, and in the second, the purchaser becomes a partner to the dishonesty, although it may be unwittingly. But leaving morality out of the case, in the long run, it will be found unprofitable to purchase the lowest priced articles. If it be groceries, they will probably be adulterated or injured in quality, or of short weight; the latter dishonesty is largely practised in cities, where active competition tempts to unscrupulous means whereby others may be apparently undersold.

Perhaps the place of greatest temptation to bargain hunters is at auction sales. I have frequently seen housekeepers return from a vendue in the country, loaded down with articles which could be of no possible use, purchased because "they went so cheap," to be stored in the lumber room until another vendue should consign them to some equally eager buyer of cheap wares. Let not the masculine readers of this part of the paper flatter themselves that this failing is peculiar to our sex. Are they not often entrapped at mock-auction shops in the City, and do they not frequently buy cheap tools for use on the farm, which cost more in poor execution, loss of time, and frequent repairs, than would twice pay for the best implements in the market? The old rule "Spend not when you may spare, but spare not when you must spend," will be found reliable for both sexes, and I commend it to the consideration of all who may be afflicted with the mania for cheap bargains. M.

How to Trap Rats.

A correspondent "W," writes to the *Agriculturist*: "Last Winter rats made their entry into my dove-cot, and in spite of efforts to destroy or banish them, they soon eat up my carriers, tumblers, fan-tails, and pouters, beginning on about ninety, and leaving seven. I read books and obtained advice from friends with an eager desire to save my favorite birds, but neither various poisons nor baited traps banished or caught a rat for consolation. Now however, I feel free from the cunning creatures, as for the past two weeks I have seen no new traces of their existence, and it is about two weeks since I caught the tenth rat, which now graces my out-house wall, with a nail through his head. Thinking that a rat when frightened was neither cautious nor cunning, I placed a common pressure spring, unbaited trap at the entrance of a rat hole, and hid it with a sprinkling of earth and light feathers. The next morning I had a "large" rat, and had no more birds taken. Eureka! Again I tried my plan, where a new hole appeared, for the floor being of earth, I filled every other hole, and the trapped rat by his struggles had filled the one at which he was caught. I trapped another—another, and again another, and until the tenth, which I trust is the last. In watching the rats prowling about, I noticed they were frequently alarmed, when they hasted into a well known retreat. They emerged carefully, but did not return so. I find therefore that a hidden trap in the path is pretty sure to catch, which a baited trap will not do. I know that this method is not always convenient, but one rat less is a national blessing in these times."

Cooking Vegetables.

A subscriber asks us how to cook Cauliflower. Boil it in water for twenty minutes or until the stalk is perfectly tender, drain and pour drawn butter over it. Some persons boil it in milk and water and think that it improves the flavor. This inquiry reminds us that too little attention is paid to cooking vegetables. The common "boiled pot" of the farm kitchen, where salt meat is cooked with a variety of vegetables, can be improved upon. There are very few vegetables that are not injured, to our taste at least, by being cooked with salt meat. Spinach or beet greens make but an indifferent dish when cooked with meat, but boiled by themselves, and then chopped and dressed with butter, they are delicious. All greens should have the water drained or squeezed out of them before they

are sent to the table. Cauliflower has its delicate flavor entirely destroyed by being cooked with meat. Simply boiling vegetables renders them eatable, but a little care in cooking and dressing them will make a delicious dish. Carrots are seldom seen upon the table, yet there is no vegetable that we prefer to nicely cooked carrots. The root should be cut into small pieces, not larger than a filbert, and then stewed with a little water, so that by the time the carrots are done, there will be but a little left; butter, salt, and a little flour are added to make a gravy, or what is better, cream may be used. Let those who like carrots at all, try this method of cooking them, and they will thank the *American Agriculturist* for the hint.

Preserving Tomatoes.

"L. G.," writes as follows: On page 183 of the June No., you speak of boiling down tomatoes one half. Now, if that is the way you do, Mr. Editor, though for several years I have been a subscriber, (a paying one,) and an admirer of your paper, still I shall never make a special pilgrimage either to "pick a bone" with you, or to eat your tomatoes. Much cooking of this fruit destroys not only its flavor, but leaves a pulaceous mass, hardly recognizable by its taste or appearance. As my wife has a more excellent way—so we think—I will describe it. Put the tomatoes into a large dish; then pour on boiling water so that the rind or peel can be more readily taken off. After which, squeeze a good part of the juice out of the tomato while it is in the hand; then cut into 2 to 4 pieces according to size. Cook for a few minutes until well heated through; bottle, using corks, thick drilling only, cemented on the under side, put on mouth of bottle and pressed down and tied. Then with a spoon dip on the wax (rosin with a little lard) until the top is covered; when cool, set in cellar and exclude the light. Prepared in this way, you will get the real, genuine flavor of the tomatoes when cooked, nearly equal to those just picked from the vines.

Parched Corn Meal.

Among the various uses to which our great American cereal can be put, the "Medical and Surgical Reporter" gives the following: "Any one who has travelled over the western prairies, is undoubtedly familiar with the kind of food named at the head of this article. The mode of preparing it is to parch the corn, reduce it to meal, and add a due proportion of sugar. Provided with this simple article of diet, the Indians, hunters, and trappers of the West will travel hundreds of miles, a very small quantity in bulk sufficing for many days. It is, without, exceedingly palatable, and is usually mixed in water when eaten.—This would be an excellent addition to the rations of our soldiers, taking the place of both flour and coffee. A small quantity of it will go a great way, and its use would economize money, time, bulk, and weight, all considerations of importance—the three last, especially so in rapid army movements." [The preparation described above, forms under the name of *Pinole*, a large share of the rations of the Mexican army, and is much used as an article of food by the Mexican people generally. When travelling in that country, it often was our principal food. We have often wondered why it was not introduced into our army, for the use of detached expeditions; it is very nutritious and requires no cooking: stirred with a sufficient quantity of water to form a kind of gruel, it satisfies both thirst and hunger.—Ed.]

How To Draw Tea.

"L," of St. Louis Co., Mo., writes to the *Agriculturist*: A few years since, the writer took tea with a relative, and was delighted with the quality of the beverage. Upon enquiry, it proved that the article was from the same package used by another friend, whose tea always tasted miserably, and the difference was wholly owing to the methods used in its

preparation. The last named person followed the usual plan of pouring boiling water upon the tea, which causes the most of the aroma to escape with the steam. The other friend adopted the following process, which I have since practised, and would recommend: Pour tepid or cold water enough on the tea to cover it, place it on the stove hearth, top of tea kettle, or any place where it will be warm, but not enough so as to cause the aroma to escape in steam. Let it remain about half an hour, then pour on boiling water and bring to the table.

Hints on Cooking.

Graham Bread.—Communicated to the *Agriculturist* by Frances K. Hurlbut, Fond du Lac Co., Wis. For enough to make two loaves, take three pints of warm water (sweet milk is better) one teaspoonful of salt, a tea-cup two thirds full of good hop yeast, and make a sponge as in fine flour bread. Keep in a warm place, and when light, work in a piece of pulverized soda the size of two peas, and Graham flour to make it just moist enough to cleave to the dish. Let it rise again in the same pan; when very light, sprinkle flour on the moulding board and mould into two loaves: when this rises again, bake from fifty to sixty minutes. The Graham flour requires soda when it is unnecessary for fine flour bread. Add three tablespoonfuls of molasses in making the sponge, if you think it improves the flavor. Persons with weak stomachs should not eat this bread until it is at least 24 hours old.

Chicken Pudding.—Contributed to the *Agriculturist* by N. E. Anderson, Franklin Co., Pa. Beat well 10 eggs, add 1 quart rich milk, $\frac{1}{4}$ lb. melted butter, pepper and salt, stir in as much flour as will make a batter. Take 4 young chickens and cut them up, then put them in a sauce pan, with salt and water, thyme and parsley. Boil these until nearly done, then take them out, and put them in the batter, and bake, and send up the gravy in a separate dish.

Baked Apple Pudding.—Contributed to the *Agriculturist* by G. W. Patterson, Clinton Co., Pa. Pare and core sour apples and fill a deep dish with them, adding a little water; then take flour with a little salt, saleratus, and shortening, (proportions as for soda biscuit,) and stir in buttermilk to the consistence of a thick batter, and spread this over the apples and bake. Serve with sauce to the taste. This makes a very nice, light pudding, good for dyspeptics.

Pound Cake and Fruit Cake.—Contributed to the *Agriculturist*, in answer to Mrs. Pry, by Susan North Barney. Stir 1 lb. of butter and 1 lb. of granulated white sugar until they form a cream. Beat the whites of 1 lb. of eggs (9 large or 10 of common size) until they will remain upon an inverted plate; stir these with the butter and sugar, then add the yolks also previously well beaten. Mix with this 1 lb. of flour, 1 small teaspoonful of saleratus, and flavor with lemon. After stirring the whole well together, pour it into two basins well buttered, and with white paper in the bottom. Two-quart basins with perpendicular sides are best.

Fruit Cake is made in the same way, except that good brown sugar is used instead of white, and there are added 1 lb. figs sliced, 1 lb. currants, $\frac{1}{2}$ lb. citron, and $2\frac{1}{2}$ lbs. of the best kind of raisins. The currants need washing thoroughly, and the seeds should be removed from the raisins. Flavor with nutmeg, cloves, cinnamon, and lemons, as desired.

Frosting.—For a half pound loaf. The whites of 3 eggs, beaten until they will remain upon an inverted plate; to which add pulverized white sugar, a little at a time, until of the desired consistence. After spreading it on the cake, set in a warm oven to dry; when thoroughly dried, spread on another layer and dry as before, until of the required thickness. [We will try to get a "Frosting Recipe" from one of the housekeepers in time for another paper—at least her frosting has a peculiar lustre, as we have seen it.—Ed.]

Use for Broken Cakes.—Contributed to the *Agriculturist* by "L. A. M." Cut the pieces in thin slices, lay in a deep dish, and pour over it a custard made as follows: Beat the yolks of 3 eggs with 2 tablespoonfuls of sugar, add 1 pint of milk and season as liked. Put it in a covered pail, set in a kettle of boiling water: when it has thickened, stir in the whites of the eggs beaten to a froth, then pour out to the cake. Soft molasses ginger cake is very good treated in this way. Several kinds of cake may be used in the same dish.

Sponge Cake.—Contributed to the *Agriculturist*, by Mrs. I. S. Kaler, Lincoln Co., Me. Beat 6 eggs, yolks and whites together, 2 minutes. Add 3 cups white sugar and beat 5 minutes; 2 cups flour with 2 teaspoonfuls cream tartar, beat 2 minutes; 1 cup cold water with 1 teaspoonful soda dissolved in it and beat 1 minute; the grated rind and juice of a lemon; a little salt and 2 more cups of flour, and beat 1 minute. Observe the time exactly, and bake in rather deep cup pans. This will make 3 quite large sheets, and it does not dry quickly as most sponge cakes do. [What if some folks beat twice as slow as others?]

Current Jelly.—The following method was recently recommended at a meeting of the N. Y. Farmer's Club. Pass the currants between rollers so as to burst each currant, and press out the juice. (Any other method will answer to break the fruit, but this is most convenient.) Place the juice in a perfectly clean copper or brass vessel over the fire, and heat it slowly until it simmers, being careful not to permit it to boil, or much of the aroma of the currant will be lost. Skim the juice until the foam ceases to rise; then pour the hot juice on to loaf sugar broken, and placed in a wooden vessel. Stir it until the sugar is melted by the hot juice, then pour into tumblers or other convenient vessels; when cold, it will be found thickened to a firm bright colored and high flavored jelly.

Rhubarb Wine.—Trim off the leaves and grind and press the stalks in any cider mill. To each gallon of juice add one gallon of water and six pounds of refined sugar, and fill the casks, leaving the bungs out. A moderately cool cellar is the best place to keep it. Fill up occasionally either from juice kept on purpose, or with sweetened water, so that impurities which rise to the surface while fermentation is going on, may be worked off. When sufficiently fermented, which will require from one to two months, bung tightly and let it remain until Winter, when it may be racked off into other casks, or bottled. Some persons refine it before bottling, by putting into each barrel two ounces of isinglass dissolved in a quart of wine.

Sweet Pickled Tomatoes.—Contributed to the *Agriculturist* by Mrs. J. Rice, Lapeer Co., Mich. Take smooth, half ripe tomatoes, scald and peel them, place them in a small-necked jar, keeping them whole. Scald vinegar and sugar together the same as in pickling for peaches, pour it over the tomatoes to cover the fruit, of which the jar must be full. Then set it in a boiler of hot water and let it boil till perfectly heated through, and then cover and seal up. They are nice either with or without spices.

Cheap and Good Prepared Glue.—Contributed to the *Agriculturist* by "L.," St. Louis, Mo. Dissolve common glue in cider vinegar, as thick as may be wanted. As it becomes too thick from time to time, add vinegar. This is as good as any that can be purchased.

Starching Bosoms and Collars.—A "Jersey Farmer's Daughter" sends to the *Agriculturist* the following directions: Pour a pint of boiling water upon two ounces of gum arabic, cover it and let it stand over night; in the morning pour it carefully from the dregs into a clean bottle, cork it and keep it for future use. A tablespoonful of this gum arabic water stirred in a pint of starch made in the usual manner will give to lawns, either white or printed, a look of newness, when nothing else can restore them after they have been washed. To every pint of starch, add a piece of butter, lard, tallow or spermaceti candle the size of a chestnut.

The Self-Important Grasshopper.

"A Grasshopper larger than a load of hay! Monstrous! Why Mr. Artist, have you not made a great blunder?" Not too fast, young friends; our artist is seldom caught napping, and even then he usually dreams something worth thinking about—let him speak for himself. He says the picture tells the old story of a grasshopper who happened to be upon a load of hay, when the horses coming to a soft spot in the meadow, stopped and seemed unable to draw it any further. The insect observing this, chirped out "I see I add too much to the weight upon the wagon, and I will therefore jump off," which he accordingly did. Just then the driver whipped up the horses, and by a great effort they took the load out of the mud, and went on easily. "See," said the grasshopper, "how much I helped them, surely the farmer ought now be willing to give me pasture the remainder of the Summer." The grasshopper in the picture is drawn of a size to show how large he thought himself. Probably the artist was thinking of something besides grasshoppers when he drew that sketch. Perhaps he had lately seen some pert youngster, who thought himself of more importance than father, mother, and all the rest of the family, who was always ready to give his opinion and advice, and who seemed to think the world could not very well move without him. Such characters are found among both young and old. The picture brings to mind an anecdote of a celebrated minister, who was on one occasion much annoyed by a busy, little, self-important man, who endeavored to draw him into a controversy. "Sir," said the little man, "what sect do you think I belong to?" "Judging from your size, and the noise you make, I should think you belonged to the *in-sects*," replied the clergyman. If on some occasion any of you should begin to put on consequential airs, and some one present should pleasantly address you as Mr. Grasshopper, you will probably be reminded of this picture and its lesson, and be careful not to assume too much importance in presence of those who happen to read the *Agriculturist*; and as their number is so large, it will be safer to always be modest and unassuming, especially as such deportment will make you welcome in any desirable society.

Ponto and the Mink.

A. H. G. contributes the following to the *Agriculturist*:—Ponto was a faithful old dog; one of the good kind that never killed sheep, nor annoyed his neighbors by sneaking around their doors. He was very jealous too about his master's premises. Minks and muskrats found no home around the "Hill side" goose pond. He was led to regard them as his special enemies. One made holes in the dam, and the other destroyed the ducks and goslings. When Ponto barked, we always knew that there was something wrong. One day, however, while all were busily engaged in making hay, his well known call was heard. There was danger of a thunder storm, and no one could be spared to answer it at the time. For more than half an hour we listened to his prolonged bow-wow-wow. This at length ceased, and in a few minutes was changed into a most piteous and smothered howl. All said that the old dog had found something, but no one could go and inquire what it was. Noon came and then at intervals only could we hear his smothered cry. The boys could stand it no longer, and when the dinner hour sounded, Dan, and Henry went down to the pond. Guided by the wailing yelps they soon found Ponto, his head and fore-shoulders buried in a hole. As the boys came down and he heard their footsteps reverberating over

his jaws, but on opening his mouth, his tongue was found bitten through in the center, about an inch from the end. The conclusion at which we arrived was this. He had found the mink that had destroyed so many goslings, and driven him into a hole. The boys knew that it was a mink by the smell. Becoming tired of barking when no one answered, he determined to sit down and watch his prisoner. For this purpose he stretched himself out half way in the hole that he had dug, panting with heat, and his tongue hanging out of his mouth. While in this position, the mink watching his chance, seized him. For the remainder of his life Ponto bore the marks of that unhappy day. Often have we distended his jaws with pride to show the scar. He never barked afterward, however, without receiving an answer; nor did he ever fail to do his duty when a mink showed himself on the premises.

A Church-going Dog.

A gentleman on Long Island owned a dog that regularly accompanied the family to church on Sunday, and also to the meeting held on Wednesday evening. If, however, for any reason none of them attended the service, the dog would start by himself, take his place where his master was accustomed to sit, and remain until the benediction was pronounced. This occurred rather frequently one season, and the sexton thinking his room better than his company, one day kicked him out. The dog immediately started for another church about a quarter of a mile distant, took his place inside near the door, and remained a regular attendant at his new place of devotion until his death, which occurred recently. The writer can vouch for the truth of this incident.

The Devoted Sparrow.

An observing correspondent of the *Agriculturist*, "A. H. G.," relates the following incident as throwing some light on the question proposed on page 153, (May No.) as to whether birds return to their old haunts in the Spring. He says: "Last Summer a Hedge Sparrow was observed one morning pecking at the basement window, and apparently trying to get in. His strange actions excited the interest of the house-keeper, and her benevolent heart immediately suggested that he must want food. When, however, crumbs were offered, he refused them with disdain—only ruffling up his feathers like a turkey cock, and hopping away until the window was closed, when he would return. Some minutes after his first appearance, the housekeeper was obliged to go up stairs, where she discovered on the mat in the hall, the ends of two wings and some feathers, very much like those upon the stranger at the window. The mystery was now explained. The cat had caught the poor sparrow's mate and he had followed her crying to the house. Day after day, and hour after hour—until the snow fell—did he appear at the window. He would not be driven away. The housekeeper was obliged to pin a paper over it for a time for his continued pecking made her nervous. From morning until night, he was there—when not at the window, usually on a hush beside it—only going away at intervals for a few minutes to feed, and then returning. When the window was left open, he would come in, and had it not been for the kindly interference of the housekeeper, himself would have shared the fate of his companion. It is only a few weeks since he returned again to his old place at the window. The snows of Winter had only disappeared when he came back. Time has not made him forget his bereavement, nor the place where

it occurred. He still runs along the grating outside and picks each pane of glass as he passes and repasses. There can be no doubt that he sees his own shadow in the glass and thinks that it is his mate. He is still alone. For the past hour I have watched him go and return at intervals of a few minutes, to follow his old habit of picking at the window. From this I am led to think that birds do return to their old haunts yearly; that in many cases they may mate for life; that there are *widowers* among them, for our devoted little friend is of the male kind. However this may be, such affection seems to prove that there is something in a sparrow akin to love.

Boys' and Girls' Garden—No. 4.

Our young friends, having carefully read the preceding chapters, understand quite well how the plant increases in height, and they have watched with interest the building up of story after story, each consisting of a piece of stem and leaf or pair of leaves. But they have noticed that the plant does not continue to increase the main stem to an indefinite height; other stems or branches, appear on the main stem. The branches grow precisely in the way that the main stem did, only instead of being fixed in the ground, they spring from the stem at the point where the leaf joins it. Branches generally appear at the place where the leaf is united to the stem. This point is called the *axil*, and anything that comes in this place is said to be *axillary*. The branch first appears in the axil of the leaf as a bud, which elongates and produces a branch in just the same way as the embryo which was in the seed, grew and formed the original stem. As the branches grow from the axils of the leaves, it follows that plants with alternate leaves will have alternate branches, and one with opposite leaves will have the branches opposite. That this is so can be seen by comparing the manner of branching of the Tomato with that of the Four O'clock. We have thus far described only the root, stem and leaf,—these being all that the plant needs to enable it to grow. But sooner or later the plant produces flowers and seed, by which it can reproduce its kind.

Flowers, which we all love so much, are of such varied form and color that most persons think the study of them must be very difficult. You have already seen how leaves vary from a very simple form; so with flowers; if you examine some simple flower and understand all its different parts, you will have a good idea of the general plan upon which all flowers are made. This plan admits of a wonderful variety, to be sure, but it only adds interest to the study to trace out these variations. The reason why we selected Flax as one of our plants for illustration, is because its flowers are readily understood, and are sufficiently large for the parts to be seen without the use of a magnifying glass. As the Flax runs up to flower the leaves gradually become smaller, and soon little buds appear, each borne on a short stem, and these after a while, open into flowers. Having the flower of the Flax, let us now examine its parts. We have had engravings made to help the description, but it is much better to have the real flower. Beginning at the bottom of the flower we find five little green leaves, much like the upper leaves on the stem; these together

Fig. 15.

form the flower cup or *calyx*, as seen in the unopened flower in fig. 16. Each one of the separate leaves of the calyx is a *sepal*. Just inside of the calyx is the showy part of the flower, the *corolla*. This, like the calyx, has five distinct leaves, or parts, called *petals*, which are much unlike other leaves, being more delicate, and of a different color and shape. The calyx

Fig. 16.

and corolla together are the *floral envelopes*; they surround, and in the bud completely envelop the other parts, which being small and not very showy, are not generally noticed, yet they are the most important parts of the

flower. The flower has some other use than to gratify our senses its real purpose is to produce seed, and this is done by the parts we are about to describe. If you look closely at the center of the flower, you will see two rows of little yellow bodies. These can be seen much more distinctly if you pull the calyx and corolla off very carefully. Fig. 17, represents a magnified figure of the flower after the floral envelopes have been removed. We find that there is no outer row of five parts called *stamens*. Fig. 18, shows the appearance of a separate stamen much more enlarged, showing its stalk or *filament* bearing an oval case or box, the *anther*, which, by the time the flower opens, bursts by two slits in its sides, and lets out a very fine powder, the *pollen*. Remove all the stamens, and the *pistil*, fig. 18, will be left exactly in the center of the flower. This consists of a roundish lower portion, the *ovary*, having five slender stalks, the *styles*, each of which bears a little knob or *stigma*. The ovary or lower part of pistil is hollow and contains *ovules*, which are little bodies that will by and by become seeds. If you have a magnifying glass you can see the ovules. Cut a flower open lengthwise with a sharp pen-knife through the center, and you will be very likely to divide the *ovary*. The ovules will be seen as little green pulpy masses. If you can not do this you must be satisfied with the representation given in fig. 15. In this figure the ovary in the center of the flower is cut through so as to show two of the ovules. These ovules would never ripen into seeds if the pollen from the anthers did not fall upon the stigmas. This in some way, which we can not explain, exercises an influence upon the ovules and causes them to grow and finally become seeds. The stamens and pistils being such important parts in the production of seed, are called the *essential organs* of the flower. If the corolla or both this and the calyx were absent, as they sometimes are, the flower could still perfect seed, but neither the stamens nor the pistils alone can produce seed. Now then, let us briefly repeat the parts of the flower: 1st, The Calyx, composed of sepals; 2nd, The Corolla, with its separate petals; 3d, The Stamens consisting of filament and anther; 4th, The Pistil, with its ovary, styles and stigmas. The parts

Fig. 17.

Fig. 18.

are one within another in the order in which we have named them, and as shown in the picture of the flower cut open in fig. 15. The corolla, stamens and styles, soon fall away, leaving the calyx and ovary. The ovary enlarges and becomes the seed pod, fig. 19, which, when ripened, will be found to contain seeds just like the one that was planted, and which, if put into the ground, would repeat over again the growth and flowering which we have described. There are some other things about the Flax flower which should be noticed: The parts are

Fig. 19.

nearly all in fives; there are five each of the sepals, petals, stamens, and styles and stigmas, and twice five seeds. Then again, the different parts are regularly placed with relation to one another: the petals are not directly opposite the sepals, but opposite the spaces between them—are alternate with them, so the stamens alternate with the petals, and the styles with the stamens. There is then a

regular plan for the Flax flower, a definite number for each set of parts, and these parts are put together in a particular way. If you will study this flower you will have a good idea of the plan upon which flowers are made, and although other flowers will look very different, yet knowing what parts to look for, and what their position should be, you will soon be able to understand their structure. Our other flowers will show some of the most common variations from the structure of the Flax, and we will try and tell you about them next month.

Frightening Herself to Sleep.

The nurse of a little girl used to frighten her when being laid in bed, by telling her that if she did not keep quiet, the rats would come and bite her; and the child dared scarcely stir for fear of the threat. On one occasion she was taken to visit friends in the country, her nurse being left behind. On her return a few days after, she was asked how she managed to get to sleep at night. "Oh," said she, "I sat up in the bed and said 'Rats! rats!' until I was so frightened I trembled all over, and then I covered myself right up, and didn't dare move again, and went right to sleep."

New Puzzles to be Answered.

No. 41. *Illustrated Rebus*. A truth worth remembering.

No. 45. *Curious Sentence*.—Contributed to the *American Agriculturist*, by "W. G. W.," New-York City. A teacher speaks with authority to one of his pupils; calls him by name, directs him to execute a lesson; designates what is to be done, and enjoins him to do it correctly. For this he uses in all, only four plain English words, and they are all sounded precisely alike.

No. 46. *Arithmetical Problem*.—Contributed to the *Agriculturist*, by P. C. Reed, Bond Co., Ill. A. and B. agree to do a piece of work, each to work as many days as the other. A. is to receive \$22 and B. \$28, of every 50. It happened that A. worked but 137½ days, while B. worked 187½ days. They receive for the work \$270; what is each man's share of it?

Answers to Problems and Puzzles.

Answers to Problems and Puzzles in June No. (page 183). No. 40. *Illustrated Rebus*. "Many a slip between the cup and lip." No. 41. *Illustrated Rebus*. "When the cat's away, the mice will play." No. 42. *Mathematical Problem*. One should have 913.7 acres; the other, 684.7 acres. No. 43. *Riddle*. A Hal.

The following have sent in correct answers: the numbers indicate the problems answered by each.

Pure and Economical Articles

FOR FAMILY USE.

Pyle's Cream Tartar,
Pyle's Saleratus,
Pyle's Baking Soda,
Pyle's O. K. Soap.

Housekeepers will find these articles reliable, and the cheapest in the end. Sold by Grocers everywhere.

JAMES PYLE, Manufacturer,

350 Washington-street, corner Franklin, New-York.

MME. DEMOREST'S MIRROR OF FASHIONS.

The magnificent Summer No. ready, 25c. Sold everywhere. Yearly \$1; with valuable Premiums. 473 Broadway. Every Lady should see it.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for \$3, or with 24 objects for \$5. Address HENRY CRAIG,

180 Centre-st., New-York.

A liberal discount to the trade.

"The CRAIG MICROSCOPES are just what they are claimed to be. Those who wish such an article, will not be disappointed, if they should obtain one of these."—N. Y. Methodist.

MR. HENRY CRAIG,

Dear Sir:—I have received the

Microscope which you sent me, and deem it the best for practical purposes. I have ever seen. I like it much better than one which I have been using that cost me \$20; and without hesitancy would recommend it, not only as an instrument well adapted to afford instructive amusement to every family circle—but as being the best I know of for "the use of the practical Naturalist."

Yours truly,

J. BODINE THOMAS.

Williamsport, Pa., May 7th, 1863.

Lands—To All Wanting Farms.

Large and thriving settlement of Vineland, mild climate, 30 miles south of Philadelphia, by railroad; rich soil; fine crops; twenty acre tracts, at from \$15 to \$20 per acre; payable within four years. Good business openings; good society. Hundreds are settling and making improvements. Apply to CHAS. K. LANDIS, Postmaster, Vineland, Cumberland County, N. J. Letters answered. Papers containing full information sent free.

Rye, bushels..... 68,600 209,900 48,500

The receipts, sales, and exports of Breadstuffs have been quite heavy during the month, as had been anticipated at resumption of navigation on the canals and rivers of the interior. The export demand was active during most of the month, encouraged by the favorable market reports from England; but, toward the close, buyers were less disposed to operate, unless at prices much under those claimed by holders, in view of the depression in the gold and foreign exchange markets, the rise in rates

on freight, and the great trouble with the stevedores and longshoremen (loaders of ships), who, having made a "strike" for higher wages, refused to work, and did everything in their power to prevent less exacting laborers from filling their places. This trouble continues without abatement, and very seriously impedes shipping operations. The Scotia, from Liverpool, arrived here on Monday, bringing reports of very fine weather, promising crops, and falling markets in the West of Europe. This news had a depressing effect on the markets here, and with the rapid decline in Gold and Sterling Exchange yesterday, holders were eager to sell, and purchasers less willing to operate. Prices close lower than a month ago, and with a strong downward tendency.... Cotton fluctuated materially, but closes rather firmly at 57c @ 58c for Middlings, with a moderate inquiry.... Wool opened heavily at drooping prices, in the absence of buyers, who had gone into the country to make purchases, but having partially returned, during the past two weeks, business has been more active, particularly in domestic fleece, and at more regular rates. Provisions have been quite plenty and have declined. The demand has been mainly for hog products. Butter and Cheese having been in very limited request.... Hay and Hops have been in fair demand, while Seeds and Tobacco have been quiet, without any remarkable changes in prices.... Petroleum has been freely offered and purchased, mainly for future delivery, at irregular prices.... Business in most other articles has been quite limited. The following table will show the present prices and the changes from last month.

CURRENT WHOLESALE PRICES.

	May 20.	June 18.
FLOUR—Super to Extra State	\$5 30 @ 5 50	\$4 75 @ 6 05

N. Y. Live Stock Markets.—The Cattle markets have been well supplied with beeves during the past month, the weekly receipts ranging from 4,600 to 5,400, and averaging 4,800. Trade has been very good and prices remarkably uniform, the variation amounting to only 1/2c @ 1 lb. The State of Illinois is supplying four-fifths of all the stock sent to this market. Prices at the latest sales were: for prime steers, 11 1/2c to 12c @ 1 lb. for estimated dressed weight of the four quarters. Medium to good cattle, 10 1/2 @ 11 1/2c; poor cattle 9c @ 10c.

Veal Calves.—Weekly receipts 1,092 for the past month. Prices higher than for several years past; good fat calves quick at 7 1/2c @ 8c @ 1 lb. live weight.

Sheep and Lambs are selling remarkably well, at high prices. The receipts have averaged only 6,797 per week, farmers keeping an unusually large number for breeding, as they find them the most profitable part of stock raising under the present rates. Sheep are now all sheared, and command 6c @ 6 1/2c @ 1 lb. live weight, if in good condition. Poor sheep are worth 5 1/2c. Lambs bring about 10c @ 1 lb. live weight, on an average.

Live Hogs.—Receipts 10,694 per week; prices 5 1/2c @ 5 3/4c @ 1 lb. live weight, corn-fed; and 5c @ 5 1/2c @ 1 lb. live weight, on an average.

FRUIT AND ORNAMENTAL TREES.

RARE CHANCES OFFERED.

200,000 Choice Fruit Trees, Vines, etc., for sale, of varied size to suit customers.

The subscriber calls attention to his unusually large stock of well grown trees now on hand, and especially to the present stock of the STRAWBERRY FRUIT, APPLE, which is the largest and finest ever offered at these Nurseries.

With twenty years of experience, by careful observation and judicious selections, he believes he is able to judge and furnish what will suit his customers, as well as the varied soils and localities, in which trees may be wanted. There is also special attention paid to local varieties, adapted to Southern and Central Pennsylvania, many of which have proven themselves more valuable, than sorts originating in a climate differing so widely from these sections.

He is also preparing a list of CLUB PRICES for those who purchase direct from the proprietor, offering rare inducements for neighbors to join together, and get trees considerably under the regular retail prices.

This note is adopted for those who may not have an opportunity to purchase from his regularly authorized agents, and hold a mistrust towards the too numerous tree vendors spread over the land.

The frequent use made of his name and establishment by strangers, to effect sales where the reputation of the nursery is known, compels him to warn all not to purchase as coming from these Nurseries—stock offered by PROPRIETORS, who do not hold an authority from the proprietor.

Local or stationed agents will be accepted, but neither traveling nor stationary agency inquiries will receive notice, unless the parties produce satisfactory reference as to their honesty in dealing with customers and employer. Send for Catalogues and priced List, which contain inducements not before offered by him. ABUNDANT AND TRUSTWORTHY REFERENCE WILL BE FURNISHED TO ALL WHO ARE STRANGERS TO THE ESTABLISHMENT.

Saratoga Springs Remedial Institute.

THIS INSTITUTION WAS ESTABLISHED TO MEET the wants of a class of Patients who feel the necessity of leaving their homes for medical aid. Its location was chosen in view of the medicinal advantages of the Springs.

Since graduating at the New-York Medical University, we have availed ourselves of the facilities found only in our large cities for the study of disease, and have given special attention to those of Women; also, of the Throat, Heart, and Lungs.

As medical practitioners we treat all diseases; but Chronic Affections claim our principal attention. While this is not a Water-cure, the invalid will find a good gymnasium, and all the facilities of a well-conducted scientific Hydropathic Establishment.

The home reputation of a physician should be the basis of public confidence. For a fuller knowledge of the Institute, we refer to our Circular, and the reliable citizens of our village.

The medical profession are invited to acquaint themselves with the Institution.

SANFORD & MALLORY'S PORTABLE FLAX AND HEMP DRESSER.

Date of Patents, Sept. 16, 1862, and April 28, 1863.

Over Fifty of these Machines have been in practical use during the past season, and so great is the demand for the coming Fall that we have adopted the following plan, viz.: That we will only make to order. Many have already sent in their orders for

Those who desire to use our Machine in dressing the crop of the present season, would do well to send their orders without delay, as all Machines are delivered according to date of order.

Made and Sold by
MALLORY & SANFORD,
HARLEM RAILROAD BUILDING,
Room No. 26, in White-st., near Centre.

Our terms are Cash on delivery of shipper's receipt or bill of lading, and persons ordering can send draft on New-York, or Treasury Notes, to some person here whom they know, or by Express, to be delivered to us on our delivery of bill of lading for shipment of Machine. Price at our Factory, at Paterson, New-Jersey, for

No. 1 Machine, (capable of dressing 2,500 lbs. of Flax Straw in ten hours,) \$355.
No. 2, \$355. No. 3, Hand Machine, \$155.

FIRST.—A machine capable of dressing 2,500 pounds of flax straw in ten hours, can be sold at the factory, ready for shipment, at \$355; and the second size capable of dressing 1,500 pounds of straw at, \$355. A third size, capable of dressing from 600 to 800 pounds of straw per day, at \$155. The smallest size weighs about 300 pounds and can be run by hand.

SECOND.—The yield of flax fibre by the use of this machine, in proportion to the weight of flax straw dressed, EXCEEDS BY AT LEAST ONE-FOURTH that obtained by any other machine or process.

THIRD.—The fibre, dressed by this machine, is much more valuable than that dressed in any other way, on account of the greater yield over the hackle.

FOURTH.—This machine is so simple in its construction and operation, that the liability to derangement is very slight.

FIFTH.—This machine does not require in its use any peculiar skill. It can be operated by boys or girls, and does not involve any risk to the hands or arms of the operatives, while the ordinary machines require the use of skilled labor, and as experience has proved, are always attended with risk to the operatives.

SIXTH.—This machine can be driven by any of the horse powers in use, and as it can be operated by ordinary farm labor, it enables the farmer to dress and prepare for market, at little expense, the flax raised by himself, thus opening to him a new and profitable occupation.

SEVENTH.—This machine is small, the largest size occupying only about four feet square, and weighing not over 1,100 pounds.

As there is a demand for larger machines for hemp, the proprietors are building such, capable of dressing two and-a-half tons of hemp straw per day.

The amount of flax fibre produced in the United States in the year 1850 was 7,806,809 pounds. Had the straw from which this amount of fibre was taken, been dressed by the Sanford & Mallory Machine, the yield would have been not less than 10,469,078 pounds. The increased product or the flax saved, at present prices, would be worth \$650,542.

When it is remembered that in many of the Western States an immense quantity of flax is raised for the seed alone, the straw being destroyed or wasted as of no value, it will readily be seen that the introduction among farmers and manufacturers of a cheap and effective machine, capable of converting what would otherwise go to waste, into an arti-

cle of great value, can not fail to produce the most important results.

It is well known that flax can be successfully cultivated in all the Northern States. If in addition to the value of the seed—sufficient of itself to pay the entire cost of cultivation—the straw can be made a source of large profit, a wide field of successful industry will be opened.

That the statements here put forward as to the efficiency and value of the Sanford & Mallory Machine, and especially as to the great saving effected by it over any other machine or process known, are rather below than beyond the fact, will abundantly appear from the subjoined reports and letters from practical flax-workers and dealers. Nothing need be added to their direct and positive testimony.

Over fifty of these machines for flax and hemp have been in successful use during the past season, in different parts of the country, and the demand for them is now large—consequently, orders for them should be made early, as the coming crop of flax and hemp will soon be ready for dressing.

The demand for flax during the past year and-a-half has quite doubled its price, and it is now used for many purposes to which it was never before applied, and for which it is found to be superior to cotton and other materials before in use. Whatever, therefore, may be the future product of cotton, the demand for flax will not diminish, but, on the contrary, increase with its new and useful applications. It is now largely mixed with woolen goods of almost every description; is used for paper, wadding, batting, belting, druggists, delaines, calicoes, stockings, felt hats, and carpeting. Should the experiments for cottonizing flax, for which Congress has made a large appropriation, succeed, the already large demand for it would not only be enormously enhanced, but made practically unlimited.

Take a given quantity of Flax Straw, either over or under retted, and pass it once through this Machine and it will invariably have lost four-fifths of the shive or woody part, without the least fibre of tow. The Machine requires two men, or boys, to tend it, and runs from eighteen to twenty hundred lbs. of straw in ten hours. There is no risk whatever to life or limb of the operator.

A dry or wet day makes no difference with this Machine, with reference to its result in the saving of Fibre.

The Machine can be seen in operation any day at room No. 26, Harlem R. R. Building, corner of White and Center Streets, New-York City, or at Mr. Harvey Wilcox's Flax Mill in Union Village, Washington County, N. Y.

This Machine with one-horse power will also run from four to six hundred lbs. of Hemp stalks per hour leaving the fibre perfectly clean and straight, with not one ounce of tow to the ton.

Those desiring Machines this fall should order at once, as we shall supply according to the date of orders.

TESTIMONIALS.

JOHNSONVILLE, N. Y., April 27th, 1863.

MESSRS. MALLORY & SANFORD:

GENTLEMEN.—I have been using two of your Patent Flax machines since the 1st of January last. I have given them a thorough test with the old brake. They will save from three to six pounds of dressed flax to the hundred pounds of flax straw (according to the quality of straw used) more than the old brake, and will break from one and one-fourth to one and one-half tons of straw per day of ten hours—do the work better than any other machine I ever saw. It takes out nine-tenths of the shive or woody matter in passing through the machine once; consequently it requires less scutching than if broken with the old brake, which does its work very imperfectly—breaking some of the fibres and taking out no shive. My men tell me they would rather rough-dress two handfuls after your brake than one after the old. The fibre from your brake is left perfectly whole and straight, which is better for the manufacturers, as it will hatchel more to the hundred pounds than after the old mode of breaking. I have had a quantity hatched that was dressed after each brake—taken from the same lot of flax, and the yield was five pounds per hundred more after your brake than after the old. The fine tow is equally good with that after the old brake, while the coarse is worth one third more per ton. I think that if the machine is properly used it is not liable to breakage.

Yours truly, WM. H. BUCKLEY

BELFAST, IRELAND, May 1st, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—It gives me much pleasure to report that the five Sanford & Mallory Flax Brakes which I have been operating in the different flax districts of Ireland have given entire satisfaction to all who have seen and used them. The saving over all other machines in use is large; on some kinds of straw, being as great as one-third. This taken with the saving in labor will give an advantage in favor of the brake of from £3 to £5, or \$15 to \$25 per day, beside increasing the value of the fibre by softening and giving it better spinning quality. In conclusion, I would say that the machine has been approved of and recommended by the leading manufacturers of Ireland, and also by the Chemico-Agricultural Society of Ulster.

Yours truly,

EDGAR FOWKS.

SPRINGFIELD, Clark County, Ohio, May 5th, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—I have tried one of your brakes, and I have run through thirty-one hundred pounds in ten and one-fourth hours, which was well broken, and every way satisfactory. I am, gentlemen, yours respectfully,

E. MEEK.

UNION VILLAGE, N. Y., May 15th, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—I have used two of your Patent Flax Brakes for the past eight months, and take this opportunity of saying that they exceed any brake I ever saw. They take out from sixty to seventy per cent of the shive or woody matter, leaving the fibre whole, and in perfect ribbons. They will save from five to eight pounds of dressed flax to every hundred pounds of flax straw over any brake I ever used. We can break from one to one and one-half tons per day of ten hours with each brake, and there is no danger of life or limb.

Yours with respect,

HARVY WILCOX.

BLOOMINGTON, McClean Co., Illinois, May 2d, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—This is to certify that I have run your Patent Flax and Hemp Brake more or less since the 1st of December, 1862; have broke western tangled straw, and I find that it works complete as it removes at least sixty-five per cent of the shive, and so loosens the rest that they can very readily be shook out, and the stock has a soft oily feel which is worth more than when it has a harsh wiry feel, which is invariably the case with the old machine. I do not hesitate to recommend it to any one as the best machine ever used for breaking flax straw, whether straight or tangled, rotted or unrotted, as my experience has proved it so to my perfect satisfaction.

Yours truly,

F. A. HAVENS.

STITTSVILLE, N. Y., April 18th, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—I have used one of your Patent Brakes for the past four months. I am highly pleased with it, so much so that I would not be willing to part with it on any conditions, provided I could not obtain another in its place. I feel that it is a very safe machine for the person who operates it; whereas the old brake is not safe, as many persons will testify who have lost an arm by them. I am satisfied that I get more flax and less tow by using the new brake, while both flax and tow are worth more in market than that in the old brakes, and certainly the new brake does not require near as much power to run them as the old one, which with many would be quite an object. My brother tells me that he has ordered another brake through your agent, to be used by us, as we are about to unite ourselves in the flax business the coming season. We will want it by the first of August next.

Yours truly, WM. B. LINK.

GREENWICH, N. Y., April 23d, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—You ask our opinion in regard to your flax machine. We must say we are well pleased with it. The machine has been in almost constant use since we received it from you something like six months since, and it, we think, works better now than when we first started it. We advise all our customers to buy your brake in preference to those we formerly made at our machine shop. Wishing you success in this great invention, we are truly yours,

RUSSIA OR BASS MATS, SELECTED EXPRESSLY for budding and tying; GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for Nursery purposes, for sale in lots to suit, by
D. W. MANWARING,
Importer, 215 Front-st., New-York.

TEETH

UPON ALLEN'S SYSTEM

CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the **TEETH, GUMS, ROOF, and RUGÆ** of the **MOUTH** are all truthfully represented, reflecting those delicate units, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.
A descriptive pamphlet may be obtained by addressing
Drs. J. ALLEN & SON, as above.

FOR FARMERS! RUNDELL'S HORSE HAY FORK!!

PATENTED APRIL 7TH, 1863.

This is the best and most substantial Fork yet invented. It is admitted by all practical Farmers and Mechanics, who have seen it operate, to possess superior advantages over all other Forks—being simpler, more substantial, working with greater facility in all places, can be elevated higher and through a smaller space. It weighs but twenty pounds, can be worked easily by a boy of 10 years, is very strong and is not liable to get out of repair.

That a Horse Hay Fork will pay, is no longer questioned by the intelligent Farmer, as it saves a vast amount of manual labor and time, which is an important consideration while labor is so scarce, and dear; besides it will frequently save its price when the Farmer has a quantity of hay to secure from the rain, as a man and two boys will, by the use of this Fork, unload a ton of hay in five minutes.

For Town, County and State Rights apply to
L. RUNDELL, Coxsackie, N. Y.
Manufactured by **GIFFORD BROTHERS, Hudson, N. Y.**

CLARK SORGO MACHINE CO.

(Successors to Wm. H. Clark.)

122 MAIN ST., CINCINNATI, OHIO.

Organized with ample capital, and employing every facility which the genius of invention has devised; using only the best materials, employing only the best of workmen, and owning within ourselves the best seven improvements upon Mills, including the original Hedges' Patent, we offer to the Public a series of Cane Mills of superior excellence. We call especial attention to our

VERTICAL MILLS of 1862, with Hedges & Clark's improvements, four sizes. Capacity 50, 80, 100 and 120 gallons per hour.

VERTICAL MILLS of 1862, with sweeps below, very convenient for a second story. Four sizes.

NEW HORIZONTAL MILL.

NEW HORIZONTAL MILL, with sweeps below.

VICTOR MILL of 1863, with valuable improvements. Five sizes.

Two **ROLL MILLS** of any size to order.

NEW BACK GEARED MILL, 4 to 8 horse power.

PLANTATION MILLS from 10 to 30 barrels per hour capacity. Larger sizes to order.

Every Mill warranted.

Also Steam Evaporators, Church, School and Farm Bells; Corn Crushers, Agricultural Steamers, Tobacco, Wine, Cider, Lard and Jack Screws, &c., &c.

Send for "The Sorgo Hand Book."

THE EXCELSIOR BURR STONE MILLS,

FOR FARMERS AND MILLERS.

Have taken the **HIGHEST PREMIUMS** WHEREVER EXHIBITED!

They may be driven by *horse, water, or steam power*, do their work as well as the best flat stone mills in milling establishments, and require but *one-half the power* to do the same amount of work. They are made in the best manner, and for farm use will last *thirty years*, and cost *nothing for repairs*.

THEY ARE GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

For Circulars and further information address

E. H. BENNET, Late Bennet Brothers,
42 and 44 Greene-st., New-York.

Important to Gardeners and Farmers. WANTED,

For Army Use, French White Turnips, Carrots, String Beans, Green Peas, Tomatoes, Cabbage, and Parsley.

Parties having all or any of the above articles, or wishing to plant on contract, will be liberally dealt with, by applying to

LOUIS A. WALKER,
5 James Slip, New-York,
or Stand 270, Fulton st. Pier, West Washington Market.

Reasons Why You Should Buy COOKS' SUGAR EVAPORATOR.

Manufactured by **Blymyers, Bates & Day,**
MANSFIELD, OHIO.

BECAUSE IT IS "The only Evaporator which has succeeded in obtaining any notoriety in making sugar."

C. & J. COOPER, Mt. Vernon, Ohio.

BECAUSE IT IS "No more trouble to make sugar upon it than to make a pot of mush."

O. N. BRAINARD, Marion, Iowa.
BECAUSE IT IS The only Evaporator which accomplishes the above results.

BECAUSE IT IS The only perfect self defeator. No chemical required.

BECAUSE IT IS From 50 to 100 per cent. the fastest boiler in the world.

BECAUSE IT IS Much lower in price than any other Pan in proportion to the number of square inches contained.

BECAUSE IT IS A perfect Evaporator and Defeator combined, and requires only one fire and one operation to finish the syrup, without the use of dampers by which a large portion of the heat is lost and the capacity of the Evaporator greatly diminished.

BECAUSE IT IS Manufactured under the original Cook Patent, the oldest of all Patents on shallow Evaporators, and which with its reissues covers all points of value in Sugar Pans. It is therefore an infringement upon no other, and **YOU BUY NO LAW SUIT WITH IT.**

Send for the "Sorgo Hand-Book."

Amalgam Bells,

At prices within the reach of every Church, School, Cemetery, Factory, or Farm in the land. Their use throughout the United States and Canada for the past six years has proven them to combine most valuable qualities, among which are **TONE, STRENGTH, SONOROUSNESS, and DURABILITY OF VIBRATION**, unequalled by any other manufacture. Sizes from 50 to 5,000 lbs., costing two thirds less than other metal, or 15 cents per pound, at which price we warrant them twelve months. Old bell metal taken in exchange, or bought for cash. Send for a Circular to the Manufacturer.

JOHN B. ROBINSON,
No. 190 William-street, New-York.

TO FARMERS

AND OTHERS.

We are manufacturing a Genuine Article of **FINE, MEDICINAL, and COARSE BONE DUST, or RAW BONE SUPERPHOSPHATE OF LIME**, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash.
Address **A. LISTER & BRO.,**
Tarrytown, Westchester Co., N. Y.,
Or Newark, N. J.

TO FARMERS.

Bone Taseu. Bone Taseu.

MANUFACTURED BY THE **LODI MANUFACTURING CO.**

The large sale of this manure, and constantly increasing demand has induced the Company to arrange for its manufacture on an extensive scale.

It is composed of **FINE RAW BONE** and **NIGHT SOIL**, free from all impurities, dried and ground to a fine powder, making it quick in its action, as well as permanent in its results.

For Buckwheat, Turnips and Winter Grain, no manure can be found of equal value for the amount invested.

It is put in new Barrels, 200 lbs. in each. One and a half barrels will manure an acre.

Price, free of cartage, \$4.50 per Barrel.

All orders, which will hereafter be filled promptly, must be directed to the **LODI MANUFACTURING CO.,**
66 Courtlandt-st., New-York.

AMMONIATED PACIFIC GUANO,

A real guano containing from seventy to eighty per cent of Phosphate of Lime, to which has been added by a chemical process, a large percentage of Actual Ammonia so fixed that it can not evaporate, making it equal if not superior to any other fertilizer.

Pamphlets with copies of Analysis by Dr. Jackson, Mass. State Assayer, and testimonials from scientific Agriculturists showing its value can be obtained from

J. O. BAKER & CO., Selling agents,
87 Wall-st., New-York.

COE'S SUPERPHOSPHATE OF LIME. PURE BONE DUST.

The exorbitant price of Peruvian Guano, makes these the cheapest and best fertilizers which the farmers can use.

OTHER FERTILIZERS OF ALL KINDS.
R. H. ALLEN & CO.,
New-York Agricultural Warehouse and Seed Store,
189 and 191 Water-street.

NOTICE.

In the Brewery of **KOEHLER & FINK, Gnttenberg**, large quantities of stable manure are for sale. Inquire of the owners.

THE NEW-YORK WEEKLY HERALD,

THE BEST AND THE CHEAPEST FAMILY NEWSPAPER IN THE WORLD!

The twenty-seventh volume of the NEW-YORK WEEKLY HERALD, the cheapest and best Family Newspaper in existence, was commenced on the 3d of January last.

The proprietor and editor now devotes especial attention to all the departments of the WEEKLY HERALD, and in

News, Literature, Fashion, War Maps, Agriculture, The Mechanic Arts, Sporting Matters, Financial Reports, Cattle Market Reports, Horse Market Reports, Business Reports, Editorials, Poetry,

and all other essentials of a First Class Weekly Newspaper

IT WILL BE FOUND UNSURPASSED.

It will be especially adapted to the requirements of a family, possessing for the fathers all the most important political, financial and commercial news; while for the ladies its carefully selected columns of literature of a higher order and fashionable intelligence will be found unusually interesting.

The WEEKLY HERALD has the advantage of all the facilities of

THE NEW-YORK DAILY HERALD,

Which is acknowledged to be the leading newspaper of the country. For instance, the Tribune, through its managing editor, makes the following admission in a letter to one of its own reporters:—

Office of the Tribune, New-York, April 28, 1862.

My Dear Sir:

The curiosity and anxiety about Yorktown is feverish, and the public like the paper best that is always giving something. If there is absolutely nothing to write about, drop a line and tell me that. The HERALD IS CONSTANTLY AHEAD OF US with Yorktown news. The battle of the 16th we were compelled to copy from it.

Yours, very truly,

S. H. GAY.

THE WEEKLY HERALD CONTAINS:

1. All the News of the week—Foreign and Domestic, Military, Political and Social—furnished by its corps of Reporters, Correspondents, and Contributors.

2. Editorials grave and gay, lively and severe, commenting upon the topics of the day. The Humorous Editorials of the HERALD are one of its greatest specialties.

3. The best, most complete, and authentic War Maps ever published in a Newspaper. Exact, reliable, minute, comprehensive.

The Agricultural Column of the WEEKLY HERALD is universally conceded to be the most useful and ably prepared article of the kind. Writers of well known ability and experience are specially employed for this purpose.

The WEEKLY HERALD will also contain Financial articles, carefully compiled by writers of great ability. Also reports of all the Markets, Horse, Cattle, Money, Dry Goods, Provisions, &c., &c., acknowledged to be the most complete and carefully edited articles of the kind appearing in any weekly journal, and all the odds and ends of useful information which any reader needs.

THE WEEKLY HERALD,

ISSUED EVERY SATURDAY MORNING, WILL BE FURNISHED AT THE FOLLOWING RATES FOR ONE YEAR.

One Copy.....\$2	Five Copies.....\$8
Three Copies.....\$5	Ten Copies.....\$15

Any larger number, addressed to names of subscribers, \$1.50 each. An extra copy will be sent to every club of ten. Twenty copies to one address, one year, \$25, and any larger number at same price. An extra copy will be sent to a club of twenty.

ADVERTISEMENTS to a limited number will be inserted in the WEEKLY HERALD.

THE DAILY HERALD. Three cents per copy. Ten dollars per year for three hundred and sixty-three issues. Five dollars for six months. Two dollars and fifty cents for three months.

JAMES GORDON BENNETT, Editor and Proprietor,

N. W. CORNER OF FULTON AND NASSAU STS., NEW-YORK CITY.

Editors publishing the above prospectus two or three times, will be entitled to an exchange.

THERE ARE NO TRAVELLING AGENTS for the HERALD.

Contents for July, 1863.

For June, July, and August Only.

A SPLENDID
Special Premium.

We know that a good Barometer is a good thing for every family. To the sailor a barometer is almost essential, and the instrument is scarcely less valuable for Farmers. It will pay a large interest on its cost every year, and very often more than pay for itself in the saving of a single crop from damage by storm. We have received many testimonials to this effect, from those who have received barometers through our premium list, and our own experience has often demonstrated the usefulness of the instrument in foreshadowing the coming storm, as well as the approach or continuance of fine weather, when

Fig. 1. Fig. 2. which has been the chief cause of breakage in transporting mercurial barometers. This new arrangement is so perfect, that with his improved mode of double boxing, the manufacturer now offers to guarantee the safe carriage of each instrument we may order, and to make good any chance loss. This guarantee places this barometer first, and we recommend it above all others for general use.

The barometers are of different forms and prices, ranging from \$5 to \$20, the price depending upon the style of finish. The tubes and working apparatus of those costing \$8 to \$20 are the same, and are supplied with inclosed thermometer, vernier, etc. Fig. 1, shows the \$8 form. Fig. 2, is the \$12 form, put in walnut or mahogany case, as desired. They are both neatly made, the \$12 size being of course the most ornamental, and the preferable instrument on this account.

We are glad also to announce that we have made a special advertising arrangement with Mr. Wilder (to continue only from June 1st, to August 31st,) by which these good barometers can be supplied as premiums, on terms that will place them within reach of many of our readers.

Here is our offer (the instruments to be sent direct from the manufactory by express, and their good quality and safe delivery warranted by the manufacturer, which guarantee we agree to see made good):—

1st.—The \$8 Barometer (Fig. 1) will be presented (with the guarantee as above) to any person who shall, between June 1st and August 31st, send fourteen subscribers to the *American Agriculturist* at \$1 a year. (The subscriptions to date January or July 1863.) See next column.

2nd.—The \$12 Barometer (Fig. 2) will be presented (with the above guarantee) to any person who shall,

between June 1st. and August 31st, send twenty subscribers to the *Agriculturist* at \$1 a year. (The subscriptions to date January or July 1863.

N.B. The subscribers can be sent in at any time between June 1st, and August 31st; but each name for the special premium should be specially noted as for this.

This premium is special, and applies only to subscribers received after June 1st, and before August 31st.

N.B. Any person who desires to get his barometer at once, for use during the haying season, or otherwise, can send the amount (\$14 or \$20) and receive his instrument, and then forward the names before August 31st.

The subscriptions for the above premiums may date January 1st, or July 1st, that is, at the beginning or middle of the volume. Any back numbers will be supplied.

Strawberry Premiums.

LAST OFFER.

Last Summer we distributed 40,000 Strawberry plants as premiums, (10 or more for each new subscriber,) sending them to all parts of the country with remarkable success. The postage on plants will be reduced one-half after July 1, and we propose to send out some more good strawberry-plants, of the very best varieties that we can obtain, as premiums to those who will, during the month of July, procure and forward subscribers to the *Agriculturist*, at \$1 a year beginning Jan. 1. or July 1. The *Triomphe de Gand* will be distributed, in part, if nothing better or more desirable is found. After seeing the fruit and observing the plants this season, we will announce what kinds will be sent out. The plants will be distributed at the proper planting season, from the last of August to about October 1st.; the time of sending will depend upon the season, and upon the locality to which they are to go. Those desiring the strawberry premiums, will please name the fact when sending in subscribers, that their names may be put down for that purpose, and they may feel assured that they will be liberally dealt with—at least as well as in the strawberry distribution so acceptable last year.

Grape Vine Premiums.—We have about 2000 Delaware and Concord Grape Vines now planted out and growing finely, all of which we can well use on our own grounds. But as we have made it a point to raise the subscription list to the highest possible limit before the middle of the volume, we still offer to send one of these vines in Autumn (safely packed, and carriage prepaid) to any one who will during this month (July) procure a new subscriber at \$1 to begin Jan. 1st, or July 1st, 1863. The vines will be sent at the proper time in Autumn, when they will have had two seasons' growth.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the *AGRICULTURIST* are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New-York City.

NEW-YORK, AUGUST, 1863.

NEW SERIES—No. 199.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

The great work of the season is over. The hot strife upon the harvest field has been crowned with victory, and the husbandman has borne away his golden trophies to the storehouse. He may now well relax his energies by a brief season of rest and recreation. There is yet much to be done before the campaign closes, and it is wise to recruit, before the plow is again driven afield, or the treasures of the cornfield secured. The writer well remembers how in younger days the prospect of a fishing excursion after harvest was like an oasis in the unending round of farm labor. It may be questioned whether in the universal strife for acquiring, American farmers are not sacrificing more than is necessary or wise. It is noticeable that farmers as a class, although surrounded by the most favorable conditions for enjoyment in life, yet bear the strongest marks of toil and care. It is not alone that the face is browned and the hands hardened by exposure and labor; the spirit of the man seems as rigid as his muscles, and he comes to regard work as the chief end of life. Here and there an open, genial countenance beaming with sunshine, shows the man appreciative of something more than money getting; and in such cases it is almost invariably found that the man mingles recreation with his labor. If there be a pond or stream within reach, he has a convenient boat, and well arranged fishing tackle; if he be where game abounds, he is supplied with rifle, fowling piece, and ammunition. "All work and no play," makes dull men as well as dull boys, and he is wise who unbends his muscles and his thoughts from severe toil before they are hardened into rigid severity. It is possible for a man to coin all his finer feelings, his better aspirations, and all the genial emotions of his nature into gold, by restraining every indulgence which interferes with making and saving money,

but there was never a greater mistake than to call such a man rich, though he may be able to count his acres by the hundred, and his bank stock by thousands. True wealth is the means of purchasing enjoyment, and of bestowing it upon others; and he most surely secures it who gives the fullest play in the right direction to all his faculties. Right here, we think may be found in large measure the explanation of the low estimate in which farming as an occupation has been held, and the lamentable eagerness with which young men have left it for other employments. Home has not been made the most attractive place, for it was only the center where money making operations by severe labor were carried on, and the indulgence of recreation and pleasure was considered entirely an outside matter, foreign to the great object of life; and hence the young have been in haste to escape to the outside, where pleasure was promised, and considered allowable. The *Agriculturist* would be untrue to its aim, if it did not endeavor to lead its readers to cultivation of themselves as well as of their grounds, and hence it is urged, that duty, no less than enjoyment require the indulgence of occasional seasons of relaxation from severe labors, and that the abundant stores of pleasure found in field and stream be freely drawn upon. A fishing excursion, a trip to the sea-side, or a neighborhood pic-nic, will furnish pleasant memories for months, and be like a sparkling stream flowing along the beaten, dusty track of every-day farm life.

Work for the Farm, Household, etc.

The widely prevalent drouth so hastened the maturity of the Summer crops, that haying and harvesting are now mostly completed, and there is a season of comparative leisure before the time for plowing for Fall grain. Profitable employment can be found in adding to the permanent improvements of the farm. A few hundred dollars expended for buildings needed for sheltering stock next Winter, may pay the interest on thousands in saving feed, and the lives of cattle or sheep. It is a most favorable opportunity for draining, particularly in swamps, which at other periods of the year are inaccessible on account of water. The fences, hedge rows, bushes and stones in meadows and other fields, claim early attention. The judicious farmer will also be on the lookout for good stock by which to manufacture his hay and grain into less bulky, more easily transported and more profitable beef, pork, and mutton, unless there be already a sufficient number on hand. If there be a surplus, the present is the time to find a market for them, before every one who is short of fodder is anxious to sell.

Buildings where grain and hay are stored need occasional examination to see that ventilation is sufficient, and that they are weather tight. A good coat of paint before the fall rains, will save much decay. Erect all needed for shelter to all

stock. Temporary sheds with roofs of straw are worth much more than their cost, if nothing better can be erected.

Bees.—Full directions for the month are given under the head of "Apiary."

Butter.—Continue to follow the directions given last month. An increase in quantity and quality may be secured by feeding cows with corn, millet, etc., from the soiling patch, unless pasture is abundant.

Cattle neglected at this season of the year and allowed to become thin in flesh, will with difficulty be prepared to pass through the Winter in good condition. If pastures are short, feed milch cows from the soiling patch, or give them a daily allowance of bran, shorts, and screenings. The extra leaves from a field of cabbages may also be turned to good account at such time. If fed immediately after milking in the morning, there will be less danger of injuring the flavor of the milk.

Cheese-Making will still be more profitable than the manufacture of butter, during the warm weather, where there are not conveniences for keeping the dairy cool. Endeavor by cleanliness and care in all the operations, to produce a first class article.

Corn.—It is not advisable to work among this crop after the roots have well occupied the ground, as they are in danger of injury by plowing. If necessary, pull out the weeds by hand. A liberal supply of green corn for winter use should be dried, or preserved in cans. For the latter purpose it should be thoroughly cooked, at least an hour, and sealed tight while boiling hot. Whole ears of corn may be preserved in strong salt brine.

Draining is now practicable in many places too wet at other seasons. Improve the present opportunity if practicable. If nothing more can be done, dig a ditch around swamps to cut off the supply of water from adjacent high grounds, and thus prepare for more thorough work in the future. Retentive soils will be benefited by underdraining. If tile can not be obtained at reasonable cost, lay drains of loose stone. Dig ditches 2½ to 3 feet deep, 40 to 80 feet apart, according to the nature of the ground, lay a course of flat stones at the bottom, and above these set large stones inclining together in wedge shape, then fill in with small stones, and cover with brush, straw, and earth. Brush drains alone, described in the *Agriculturist*, Vol. XX, page 169 (June No.), will amply repay their cost in many situations where better material can not be readily procured.

Fallows should be plowed if the weeds are preparing to ripen seed. They may thus be made to fertilize the ground from which they have drawn part of their nourishment. If left to mature, their produce will be a great hindrance

to future crops, and require much more labor to eradicate them, when they are thus multiplied.

Fences.—Arrange fields so as to need as few fences as possible, and keep these in good repair. Allow no hedge rows to line their sides, and extirpate all weeds which are ripening seeds along their course, especially in the corners. Let road and line fences especially, be kept up to prevent incursions from the stock of neighbors. Much vexatious litigation might be thus prevented.

Glean all fields of grain with the horse rake. Enough may be gathered after the most careful harvesting, to amply repay for the labor. The resulting grain should be immediately threshed out to be fed to stock, as it will usually be too much filled with foul stuff for making good quality flour.

Hay not yet secured, is worth something for bedding, if not for feeding. Gather all possible from swales and other waste grounds. Salt marsh hay should be stacked where it will not be carried away by high tides, or better, where practicable, stored near the barn, to be used during Winter.

Horses are better kept in the stable away from the flies and hot sunshine during the present month, except at night, when they will enjoy a run in the pasture. Provide fly nets for teams in use, and frequently wash them with a decoction of walnut leaves to repel insects.

Manures.—Continue to collect from every available source. Provide an abundant supply of swamp muck for use in the stables and sheds next Winter. If there is no swamp in the neighborhood, the settlements at the bottom of ponds now dry, or sunken spots at the foot of hills, will furnish excellent material for composting with stable manure. The carcasses of all animals dying upon the farm should be covered with a foot or more of muck or earth, which will absorb the gases from their decay, and furnish valuable fertilizing materials.

Meadows newly mown are much benefitted by top-dressing with fine manure. Remove all bushes, rocks, and other obstructions to the mower. Do not allow stock to graze upon them until the grass is well started.

Millet or Hungarian Grass, should be cut for curing before the seed has ripened. Experience has shown that the seed is not safe food for stock.

Outs.—Cut before ripe enough to shell, or just as the grain has passed out of the milk. When harvested at this stage, the straw, if properly cured, is valuable for winter feeding.

Pastures, when eaten very closely and burnt by the sun, will be much benefitted by top-dressing with well-rotted manure. A mulching of straw would be better than nothing. Occasionally scatter cattle droppings with a mail. Cut all weeds before they ripen seed. Sow salt about the roots of thistles to attract the sheep and other stock to destroy the young shoots.

Potatoes.—Unless signs of decay appear, it is considered best to allow them to remain in the ground after ripening, rather than dig them early, if they are to be stored. Those largely engaged in their culture will be interested in the description of the newly invented digger on page 233. Set out late cabbages, or sow white turnips where early crops are harvested. Collect tops for the compost heaps, but burn weeds of any kind that have seeds nearly or fully ripened.

Poultry.—Allow them the range of grain fields after the crops are harvested. Confine them in the houses until noon, that they may deposit their eggs on the premises. Commence to fatten early, as they will be prepared for market more easily than in cold weather, and prices will be better than later in the season.

Root Crops.—Keep well hoed, and thin out where the plants are crowded. A top-dressing of superphosphate hoed in, will be beneficial on poor land.

Rye.—Harvest any remaining. Glean the fields with the horse rake, and thresh out for grinding

for stock. Select the best for seed; thresh as early as practicable, and store by itself.

Sheep are worth especial care in the present time of high prices. Many will be disappointed in the hopes of great profits from want of skill or management. Separate all rams from the ewes, and give the lambs rich pasture by themselves or with the yearlings. Keep a few older wethers with them as leaders. Examine the bags of ewes a few days after removing the lambs, and milk them occasionally if the bags be caked. Salt freely, and apply tar to their noses to repel the fly.

Swine relish green food, which keeps up their appetites, and improves their condition. Unthreshed pea vines are excellent for this purpose. Green clover is also relished. Weeds and refuse from the garden will be worked over by them into valuable manure. Commence to feed with grain early; it will show itself in the increase of pork more rapidly than later in the season when the weather is colder. Early made pork also usually commands the best price.

Timber.—Cut any needed for building, fencing, etc., peel off the bark, and put under shelter if not wanted for immediate use.

Timothy may be sown this month with prospect of a good crop next year. If to be put in with winter grain, next month is a better time.

Turnips.—Sow strap-leaf or flat varieties among corn, where early potatoes have been harvested, or on other vacant ground. Repel the fly from the young growth by sprinkling with soot or ashes.

Winter Grain.—Plow early and harrow thoroughly several times if sod ground is devoted to this crop. It usually succeeds best after oats, fallow, or some early hoed crop. Sow late this month or early in September.

Orchard and Nursery.

We hear very differing reports concerning the orchards. In many places where there was an abundant show of blossoms there is a great lack of fruit, while in other localities there is a promise of a very fair crop. From all that we can hear we infer that there will be a moderate supply at best, and in view of the great demand there will be for all kinds of dried and preserved fruit, unusual care should be taken to prepare all that cannot be disposed of in the fresh state. Early apples and pears, as well as peaches, will need to be gathered this month. In gathering, precautions should be taken not to injure the fruit or the tree. We have not seen many trees this year disposed to overbear. Thinning may yet be done where it is necessary.

Borers.—The eggs of these hatch at this season, and the young borer will soon make his way into the wood. Use lye or soft soap upon the trunks.

Budding.—This operation should continue as directed last month. The stocks should be worked only when the bark peels or "runs" freely, and well-formed buds selected for use. Use the greatest care in keeping the varieties properly labelled.

Evergreens.—Though May is the preferable month for removing evergreens, it may be done from the middle of August to the middle of September, if care be taken to move the trees with a good ball of earth. Choose a damp time for the operation. If the soil is dry, water well and put an abundant mulch around the roots. Large stones placed over the roots are better than stakes, to protect the tree from being disturbed by heavy winds.

Layers may be made from the wood of this season's growth as soon as it is sufficiently mature.

Seed Beds.—The young seedling fruit stocks and tree seedlings generally, especially those of evergreens, are apt to suffer this month unless they are watered and partially sheltered from the hot sun. Brush may be stuck about the bed to afford a partial shade. Screens made of lath or thin slats are often used. Keep the seed beds free from weeds, and stir the soil to promote early maturing.

Water.—In August the trees which were transplanted in the Spring may suffer from the effects of drouth. A thorough watering and subsequent mulch will usually restore and save a drooping tree.

Weeds.—These must be kept down not only between the rows, but among the trees in the rows. The cultivator or plow should be run through the rows frequently, and the soil near the trees worked with the hand hoe.

Kitchen Garden.

It is a good thing to have a garden. It is a pleasure to see the things grow, and to watch the maturing of vegetables planted by one's own hands. Then what a variety of delicious healthful food is now being daily furnished; fresh too—not carried a long distance to market and then allowed to wilt and lose its sweetness by long exposure on the huckster's stand—but only a step from the garden to the kitchen. We repeat it is a good thing to have a garden. In a garden of any considerable size, there is always a surplus which should be dried, salted, or bottled, as the case may be, for winter use. The heavy work is over and but little remains to do, but to keep the crops growing and the weeds from thriving, to clear off early crops and put in a few late ones.

Asparagus.—The dense growth of tops will help to keep the weeds in tolerable subjection. Large weeds will need hand-pulling. If seeds are desired, they may be collected as soon as they ripen, and sown at once, or preserved till Spring.

Beans.—Some of the early bush varieties may be planted for a crop of late string beans, or for pickles. String beans may be preserved for winter use by preparing them as if for cooking and packing them in a jar or keg with alternate layers of salt. Some persons scald them before putting them down.

Beets.—Thin those sown last month. In pulling the early sorts for use, take from where they are thickest. This vegetable is much better when grown rapidly, and it will pay to water small beds in dry weather, and give liquid manure.

Cabbages and Cauliflowers.—The early sorts are now ready for use. Keep all well hoed; their growth will be more rapid, with a consequent increase of tenderness. Set out the remaining plants for the latest crop.

Carrots.—Where young carrots are preferred to full grown ones, seed can be sown now.

Celery.—Earth up that set out early, as soon as sufficiently large. Prepare trenches as directed in July and transplant the late crop. Shorten the roots of the plants and remove the large straggling leaves before setting. If the weather be hot, shade for a few days with brush laid over the trenches, or with boards, and keep well watered. Some cultivators prefer to grow their celery upon the surface and leave the hoeing until it is taken up for the winter. We have never tried this method.

Corn.—Forward that planted last month by thorough hoeing and stimulate with a little hen manure if backward. The early sorts will now give a supply. Leave the earliest and best for seed.

Cucumbers.—For pickles gather when of a size to suit the fancy; most persons prefer them quite small. Preserve a sufficient number of vines to produce seed and remove all fruit from them, except that intended to ripen.

Egg Plants.—Hoe thoroughly and hill slightly, and forward by all possible means. If the fruit touches the ground, there is danger of its rotting; place a shingle or a handful of straw under it.

Herbs.—Gather and dry as soon as they flower.

Hoe and Rake.—The constant use of these tools is required to keep the garden neat, and it will, by loosening the surface, promote the growth of the plants. We have before recommended the hayonet hoe; it will pay to get one even at this late day; for working among cabbages, lettuce, etc., there is nothing like it, and for small gardens hardly any other hoe is needed.

Lettuce.—Those who like salads through the season, can easily keep up a supply by sowing at intervals. Choose a rather shaded place for sowing in hot weather, and give water as needed.

Melons.—To get fine well ripened fruit, a little pains should be taken. If the vines are neglected, twice as much fruit will set as can be ripened, and the frost will cut off a large lot of half grown melons. Take off all the fruit except 3 or 4 specimens to each vine. The ripening may be hastened by putting straw, or a piece of board under each melon. An occasional careful turning will cause them to ripen equally.

Onions.—In many places these will be ready to harvest by the last of the month. When the majority of the tops have fallen down, pull the crop; let them remain a few days in the sun, and then stack them in heaps or two or three bushels each. Most cultivators last year, marketed their onions as soon as harvested and at a comparatively low price. Onions properly cured and stored in a cool place, so that air will have free circulation, can be kept for a long time. See our work on onion culture.

Peas.—Be particular in saving seed. Clean the ground of stalks, which may be fed to swine or sheep, and occupy it with turnips, late cabbages etc.

Potatoes.—In digging potatoes for family use, it is the best plan to bury the tops as you dig from time to time, they afford an excellent manure.

Seeds.—Use every care in saving from the best specimens. Do not trust to recollecting the sorts but keep a label of some kind with them from the moment they are gathered until they are finally put away for use next season.

Spinach.—Seed may be sown at intervals to yield a late supply.

Squashes.—The summer varieties should be picked and used or marketed before they become too hard. Save seed from the earliest. The winter sorts are now too large to work among with safety. Continue to watch for the squash bugs and borer, and destroy insects and eggs.

Tomatoes.—Pick off the growth which will not perfect its fruit. The large green caterpillar will be busy this month. Look over the vines and hand-pick them. A single one if neglected will strip a vine of leaves in a few days.

Turnips.—These may be sown to take the place of crops which have been removed. The Red Top Strap-Leaf is one of the best for late sowing. White French and Swedes may be transplanted if they stand too thick in the beds. They can be transplanted as readily as cabbages.

Watermelons.—These need essentially the same treatment as melons.

Weeds.—Exterminate long before they can perfect their seeds.

Fruit Garden.

Blackberries.—There is every prospect of an abundant crop of this most delicious fruit. The New-Rochelle or Lawton should not be picked until it is fully ripened. If there is more fruit than can be consumed in the fresh state, it may be preserved in bottles, dried, or made into jam.

Currants and Gooseberries.—The season of currants may be much prolonged by shading the bushes. Where it is desirable to do this, a portion of the bed may be covered with a cheap awning. As soon as the fruit is off, prune the bushes, taking out from one third to one half of the old wood. Read article on page 242, where we mentioned only the Cherry and White Grape, and omitted to add that the Versailles (red), and Provence (white), were also desirable kinds.

Grapes.—The young vines should be treated so as to produce strong and well ripened wood only. See article on page 146, in May *Agriculturist*. In fruiting vines, the branches which have been pinched back, may throw out side shoots which should be removed. Keep well tied to the trellises. Pick

off caterpillars or dislodge them by a strong stream of water from the Aquarius or other garden engine. Mildew has appeared in some localities. We know of no better remedy than to remove the affected branches. Sprinkling with sulphur stirred in water may be tried as a preventive.

Raspberries.—As soon as the fruit is off, the bearing canes should be cut away. The new shoots of this season's growth will bear the fruit of next year, and their development should be hastened: cut out all but two or three of the strongest shoots, which should be kept tied to stakes or the trellis, and fork in well-rotted manure around the roots.

Strawberries.—Where it is desirable to multiply plants, give the runners their own way, otherwise cut them off as they appear. We have said sufficient on strawberry culture on other pages.

Flower Garden and Lawn.

This is the month in which the garden and grounds generally present the fewest attractions. The early flowers are gone, and it is too soon for the Autumnal ones. General watering in a time of drouth, can only be practised in gardens of very moderate size; still those plants which droop under the continued heat and dryness, should be saved by a special watering. Remove the earth near the roots and give a copious watering, and return the earth after the water has soaked away. This will be more effectual than surface watering.

Box Edging.—Give its last clipping early in the month, and keep well hoed.

Budding may be done on the shrubs which it is desired to propagate in this way, such as Oranges, Lemons, Magnolias, Roses, etc.

Bulbs.—Hyacinths and Tulips should be allowed to remain in the ground until the leaves commence to wither, when they should be taken up and kept in a dry place until time for the fall planting.

Climbers.—See that the supports are of ample strength to hold up the rapidly increasing weight.

Dahlias.—Keep well tied up to stakes according to directions given on page 211, last month. As soon as their beauty is passed, the flowers should be cut off. Watch for and destroy the borer.

Fuchsias.—These are propagated from cuttings with the greatest ease, by the method given on page 244. They are deservedly increasing in popularity as among the choicest ornaments of the flower garden.

Grass.—Whether on the lawn or as edgings, treat as directed last month. New lawns may be seeded; add a little rye to the seed; this will afford protection to the young grass.

Gravel Walks.—Keep free from weeds, in good condition, by the use of the hoe, rake, and roller.

Hedges may now receive their final clipping.

Hoe.—Keep the soil stirred by free use of the hoe and rake.

Insects.—Every chrysalis or cocoon should be destroyed as it contains the germ of future trouble.

Layers.—Shrubs and vines can be layered, and many of them will be rooted by Autumn. Those laid down in the Spring, if well rooted, may be taken away from the parent stock and planted elsewhere.

Mignonette.—If the seeds are sown now a late bloom may be had. It may also be sown in pots for flowering in the house during Winter.

Pelargoniums.—Trim to a compact form, and use the cuttings to start new plants. Remove the flower stalks as soon as the blossom falls.

Potted Plants.—Do not let them suffer for lack of water. Loosen the soil and remove all weeds.

Roses.—Continue to use whale oil soap against the slugs. Put down branches of the new growth as layers. If the remontants were properly cut back, they will now give a fine show of flowers.

Seeds.—Care should be taken to secure seed of the

finest specimens only. Biennials and perennials if sown as soon as the seed is ripe will give a bloom during the next season and thus save a year.

Verbenas.—Secure a stock for wintering over, either by layering or by striking from cuttings.

Green and Hot-Houses.

The work here is mainly that of preparation, as most of the plants are out of doors. If new structures are needed, they should be built at once. All repairs and painting are to be completed some weeks before the plants are returned to the house. A supply of potting earth should be laid in, and a stock of coal or other fuel secured. Cuttings of plants for early Winter blooming may be put in and those already started, potted off.

Apiary in August.

Prepared by M. Quinby—by request.

The moth will continue to prowl about the hives at night during the warm weather of this month. The female has a few hundred eggs to leave somewhere, and any colony not strong enough to keep her at a distance, will have to yield its wax to feed her progeny. Continue to set dishes of sweetened water about the hives at night. This insect has an appetite for strong drink, and will indulge like a human being, until destruction overtakes her. Some of them will drink even to bursting, and will fall into the liquid mire, and wallow about in it, delightfully intoxicated until morning; then comes the reckoning. Strain them out and feed to chickens. The bees of any diseased stocks that have been neglected may yet be driven out; they will probably do something; what they do make will be good for another year, when it is not enough for winter. Where Buckwheat is a general crop, strong colonies that are full, will store from twenty to thirty pounds of spare honey from its flowers. Give abundant room for this, by the addition of boxes. Boxes nearly full of honey from clover, should be removed in the early part of this month. If sent to market, and they contain but very little buckwheat on the outside, they will appear to be wholly of that quality, and will have to be sold for a corresponding price.... When a colony is much weakened by over swarming, and has left boxes half filled, with the cells generally unsealed, it is quite common for the bees to remove every particle of honey to the combs below. This is particularly the case where there is no buckwheat crop. Strong swarms may, at the same time, be gradually filling boxes. Watch closely, and take off as soon as they commence removing it. Being free from pollen, it is very nice for the table, even if it is not sealed. When the supply of honey has very much failed, there is some risk of changing from one hive to another; instead of having a box finished, we may lose what we have already. Swarms that issue this month, rarely make enough for Winter, they are usually worth but little; the bees are needed in the old stock to keep it strong for winter. If there is any queenless colony that needs a part, divide them, give half the bees with queen to that, and return the balance to the parent hive. When not wanted in this way, take away the queen and return all the bees. They seldom issue again at this season. Boxes of honey kept through the warm weather, will sometimes show the moth worm. A streak of white powder-like substance is first seen on the surface of the comb; in a few days the web will appear. Put in a barrel or box, cover closely, and smoke with brimstone.... Any one having the Italian bees and being surrounded by a large number of black or natives, will find it difficult to keep them pure. The queen meets the drone away from the hive, and a queen and a drone kept in colonies three miles apart will sometimes meet. On this account there is an advantage in rearing queens late, say October, when all the native drones are usually destroyed. To secure drones of the Italians at that time, select now a colony of the most beautiful ones, take away the queen, and destroy queen cells that are made eight days afterward. Drones are not destroyed here unless destitute of stores.

The hive that is used for this purpose can be made to winter a colony afterwards, if it has sufficient honey. The bees from some light one may be introduced in November or December. The Italian queen can be introduced in November as well as any time.

The Crops—General Prospects.

Mr. Judd, Editor of the *American Agriculturist*, writes from Grinnell, Poweshiek County, Iowa, July 18th: "...In passing over the great belt of country, lying in almost a direct line between here and New-York, I have carefully observed the growing crops, and conversed with many farmers in regard to the prospects. As the result, I conclude that the wheat crop will be fully an average one. At some points there was considerable winter-killing, and the fields show but a slim stand. In other places the stand is large, and the heads well filled. The favorable weather for harvest is telling well. The berry is large and plump, and very little will be lost by rust, or injured by rains in the gathering. Though there is a scarcity of help, enough appears to be found to gather the crop.—Oats look well in many places; in others they are heading out short and slim, owing to dry weather. The first hay crop was generally fair—frequently large. The drouth now prevailing is drying up the pastures. Corn also looks well in most sections, but in limited localities, it is badly injured by dry weather. Unless copious rains fall ere long, the crop as a whole, will be below the average.

Great American Exhibition of Pumpkins, Squashes, and Ornamental Gourds.

The **Second Annual Exhibition of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS**, at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, **Nov. 4th, 1863**, at which the following Prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

A—For the <i>Heaviest</i> Pumpkin or Squash.....	\$10.00
B—For the 2nd <i>Heaviest</i> Pumpkin or Squash...	5.00
C—For the 3rd <i>Heaviest</i> Pumpkin or Squash....	3.00
D—For the Best Pumpkin or Squash for <i>cooking</i> ...	5.00
E—For 2nd Best Pumpkin or Squash for <i>cooking</i> ...	3.00
F—For the largest yield on a single Vine.....	10.00
G—For the 2nd largest yield on a single Vine....	5.00
H—For the largest and finest collection of <i>Fancy</i> or <i>Ornamental</i> Gourds*.....	7.00
I—For the 2nd largest and finest collection of <i>Fancy</i> or <i>Ornamental</i> Gourds*.....	4.00

*All to be grown by one person and to be accompanied by positive evidence from the grower, and one disinterested person who assists in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 15th, and deliver specimens for competition on or before Nov. 2d. Specimens to be delivered free of charge.

Note 3.—The same specimen can compete for only one of the premiums offered above.

Containing a great variety of items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

Working under Difficulties.—On another page will be found a most interesting letter from the absent Editor of the *Agriculturist*, describing the harrowing scenes witnessed upon the ground after the great battle of Gettysburg. It was fortunate for him and for our readers that he was not compelled to collect and work over materials for the regular monthly issue in the neighborhood of that conflict while it was raging. Not but that he might have accomplished it, but it would have been an up-hill job. Quite unexpectedly the remaining editors here in New-York have found themselves surrounded by a struggle, not indeed so tremendous as that in Pennsylvania, but one for a time so all-absorbing as to make work on the paper next to an impossibility. The events to which we refer, the breaking out of the most violent riot ever witnessed here, conducted by a mob unparalleled for ferocity, and the reign of terror in some parts of the City for several days, have been duly described in the various newspapers, and we need not here chronicle them. Suffice it to say that

our office being situated in immediate proximity to the Times and Tribune offices, was at headquarters where excitement was felt, and on several occasions it became the duty of the able-bodied members of our establishment to stand on guard for the preservation of the property and peace of the neighborhood. This, with the fact that the office of the parties where the paper is printed was closed for a time, from fear of threats by the mob, will account for the delay of a day or two in the issuing of the paper, and will insure the indulgence of our readers, and their charity for any imperfections that may have escaped notice.

Our "Gift Enterprise."—We have come to it at last. After showing up gift enterprises for years past, we have gone into a sort of "gift enterprise" on our own hook. The details are given on page 241. It will be seen however, that there are no chance Prizes in this enterprise, and no money required—the "gift" is to be a genuine one, and all on our side. The *Agriculturist* for next year will be as good as it has ever been, and partially better, and will be amply worth not merely the dollar subscription, but many of them, while every person paying in his dollar will not only get the paper, but one or more plants of the greatest strawberry the world has ever produced. First come, first served, will be the order. A thousand names are already down for next year. The next subscriber coming in for 1864 will go down next, and so on. As fast as plants can be produced, they will be sent out, beginning with the first on the list. All old subscribers, renewing for 1864, if their time does not already extend to that year, will of course come in for a "gift." New Subscribers will have the gift also. We ought to have ten or twenty thousand of them, but if all the present subscribers renew and get the strawberry plants we shall be satisfied. Our family is now nearly as large as we can superintend and provide for.

The Agriculturist as a Premium.

—W. F. Williams, Clay Co., Ind. Many hundred copies of this journal have been yearly distributed as premiums by the County Agricultural Societies of different States, and numerous correspondents have assured us of their satisfaction at receiving what they came to consider a valuable prize, when they became fully acquainted with it. There are many advantages in offering some good agricultural journal in the list of premiums; we know of nothing better calculated to stimulate improvement upon the farm and in the garden.

Wool-Growers' Association.

—Samuel Ingels, Sec., writes that a Wool-Growers' Association has been formed in Mahaska Co., Iowa. At a meeting held July 16, there were represented 19,067 sheep, principally Spanish Merinoes, and it is expected that the number will be considerably increased at the next meeting. We are glad to note that wool-growers in other sections are forming similar associations, as by this means their interests can be protected and forwarded.

Sale of Sheep at Thorndale.

—We have just learned that a large number of the first-class Southdown Sheep belonging to Samuel Thorne, will be offered for sale to the highest bidder without reserve, the coming Fall. The noted excellence of this flock for purity of blood should attract a large number of buyers. Full particulars are given in an advertisement on p. 251.

Strawberry Questions.—Either on account of our Exhibition or some other cause, there is just now a great interest manifested in the strawberry culture. We have numerous letters upon the subject, and many of the writers will find their queries answered in the article on page 241. We answer a few others here, and to save room do not mention the names of the inquirers.... We know of no remedy against grubs where a strawberry patch has been made on an old pasture. Better begin again on other soil.... The Hovey's Seedling is still a favorite berry around Boston, and in some other localities. The reason why it is generally discarded, is because it is a pistillate berry and needs a fertilizer, while there are plenty of perfect berries quite as good. The inquirer's total failure is probably due to the fact that his other kinds do not bloom at the same time with the Hovey. The Boston Pine is found to answer best as a fertilizer.... The Austin is not a first-class berry as to flavor. It stands dry weather remarkably well, and is a desirable family sort. It is remarkably prolific. We had on our table from G. K. Riker, of Stamford, Conn., one hundred and twenty-six berries from a runner set out in the Spring of 1862.... Trembley's Union is a most beautiful berry. Some of our fruit men think it the same as Trollope's Victoria, but admit that they never saw that variety bear like the Union. With Mr. T. it has been very productive, and has remained long in bearing.... We consider the Crimson Favorite a first-class berry, and have Mr. Fuller's assurance that it is a good bearer.

Sowing Strawberry Seed.—A Subscriber. They should be sown as soon as the fruit is ripe. They will come up much more freely than if kept until the following Spring.

Plants for a Name.—S. Elliot, Cumberland Co., Pa. The specimen is *Tradescantia Virginica*, or Spider-wort. It is much cultivated, and though its flowers keep open for only a portion of the day, it is worthy of a place in the garden. There is a variety with pure white flowers, which contrasts well with the blue... W. B. W., Buel, N. Y. The leaves and flower are those of the *Saracennia purpurea*. It is not a rare plant in our cold swamps, and is known by various popular names such as; Side-saddle Flower, Pitcher Plant, Whippoorwill's Shoe, Huntsman's Cup, etc.... J. W. Bancroft, Barry Co., Mich. Your specimen is "Cotton grass;" it is not a proper grass, but belongs to the sedge family. Its botanical name is *Eriophorum polystachyum*. *Eriophorum* means wool-bearing, and is given on account of the long hairs upon the flowers.... A subscriber, St. Joseph Co., Mich. The leaf and flower are those of the American Columbine—See July Basket, page 198.... Irene Cole, White Co., Ind. Your No. 1 is the Trumpet Creeper, (*Tecoma radicans*), a very pretty climber, but quite distinct from the Virginia Creeper, which has very minute flowers. No. 2 is *Calystegia pubescens*. *Spectabilis* is accented on the second syllable.... Martin Allen, La Salle Co., Ill. The plant sent is *Tradescantia*, noticed above.... S. H. Marrow, Androscoggin Co., Me. Your specimen is *Saracennia*, and is already noticed in this item. There are other "pitcher plants," but none grow in your State.... "F. G. C.," Monterey, Ind. The plant is American Columbine, mentioned above.

Propagation of Plants.

—Baltimore. We know of no work exclusively devoted to this, though the various works on gardening treat of it to some extent. The case for striking cuttings is figured and described in the *Agriculturist* for April, 1860.

Saving Maple Seeds.—John Moore, Cook Co., Ill. The seeds may be mixed with dry sand and kept in a dry place out of reach of the mice.

Work on Gardening.—Mrs. Agnes Kemp, Penn. We know of no better work for your purpose than Watson's American Home Garden. It is in many respects the best work on gardening yet published in this country. Sent by mail from this office for \$1.50.

Work on the Cultivation of Trees.

Martin Allen, LaSalle Co., Ill. We know of no American work on the cultivation of trees for timber. The French work of Du Breuil is a good one, but it has not been translated. Emerson's Trees and Shrubs of Massachusetts has a little upon the subject, but that is out of print.

Fruit Books.

—To several Inquirers. Downing's Fruits is the best descriptive work, and Barry's Fruit Garden, the best for culture, propagation etc. Both are in our book list and will be sent by mail at the prices there given. The Prairie Farmer has not suspended; the mail is probably at fault.

Pure Squash Seeds.

—J. Patterson, Ohio, If but one kind is cultivated there is no danger. Where there are other sorts in the vicinity, the artificial fertilization must be practised. The fertile flowers, those that set a fruit, must have the pollen of the barren ones applied to them. This must be done before the fertile flower opens; it should be taken when just ready, and will open with but slight force and have the pollen or dust from a barren flower rubbed upon the pistils. The flowers thus treated must be protected from the visits of bees, by means of gauze, until the fruit begins to grow.

Saracennia for Small-Pox.

—John Keen, Wayne Co., Ill. We believe that this plant has not, upon trial, proved to have any particular curative properties. It is common in swamps, and is known as the Pitcher plant. Its hollow leaves, which are shaped somewhat like a horn, and hold water, distinguish it from all other Northern plants.

Gladiolus Bulbs.

—R. H. Martin, Sussex Co., Del. These can generally be left in the ground without risk. If we had any very choice sorts, the hardiness of which was not proved, we should take them up to make sure of them.

Farms for Sale.

—Two or three of these will be found among the advertisements on the last pages of this number, among which is one in a good agricultural and stock region of Illinois.

Hungarian Grass for Sheep.—H. M. Taylor, Cooper Co., Mo., writes to the *Agriculturist* that his experience in feeding hay from Hungarian grass has been unfavorable. He lost eight sheep from a flock of one hundred which were kept on this fodder. The seed was ripened and unthreshed. He recommends to allow no seed to ripen on grass intended to be cured for winter feeding stock.

Feeding Sheep with Corn.—James McClure, Logan Co., O., in answer to the question: "How much wool will a bushel of corn make, when fed to sheep?" says that last Winter he fed more corn to his flock, and gave them better shelter than ever before, but that the fleeces were lighter this season. This appears to be contrary to the general experience of sheep-breeders. We should like further details of those having experience in the matter, whether favorable or otherwise.

Wool Suit.—The Wool-Grower gives the particulars of a lawsuit brought to recover damages against a farmer for enclosing "tags" and dirt in the centre of his fleeces, and selling them as fine wool in good condition. It was argued that it was customary for farmers to roll up the tags in the wool, and that there was no intention to deceive; also, that the purchaser accepted the wool, which he might have inspected if he chose to do so. On the other hand the Court held that as the wool appeared outwardly in good condition, it presupposed it to be so internally, and that the purchaser was not bound to open every package to see if it contained dirt, etc. Judgment, against the farmer, and very justly, we think.

Sale of Good Sheep.—By referring to our Advertising Columns, it will be seen that another opportunity is offered to the public to procure Southdown sheep of the choicest quality at the sale of Mr. J. C. Taylor, Holmdel, N. J. It will be remembered that this flock is largely made up of sheep purchased from the collection of Jonas Webb, Mr. Taylor having secured some of the choicest animals, among them the prize buck, for which \$1300 was paid.

Lice on Animals.—G. B. Talcott, Tioga Co., N. Y., writes to the *Agriculturist*, that he has found strong brine a complete remedy for lice upon horses or cattle. The animal should be thoroughly washed with it, and a few applications, will destroy nits as well as the parent insects. [Easily tried, but perhaps hazardous.]

Gophers.—W. A. Vaughn, of Crawford Co., Wis., is in trouble with the gopher, a sort of ground squirrel, or marmot, with large pockets in each cheek. These burrow in the ground and completely undermine it. A Minnesota friend informs us that they get rid of them in that State by poisoning them with strychnine. After the crop is sown, some grain which has been soaked in a solution of sulphate of strychnine in water, is strewed about for the benefit of the gophers. Strychnine in very small quantities is very fatal, and the animals can not go far after they have eaten it.

Striped Bug Antidotes.—Jesse Cendrick, Henry Co., Ohio, writes to the *Agriculturist*, that there is nothing like lime for destroying or driving away the squash bug. He punches holes in a tin box, fills it half full of fresh slaked lime and shakes it over the plants, repeating the process, when necessary. Wirt C. Williams, Dane Co., Wis., writes that he has succeeded in repelling the bugs by saturating a cloth with kerosene oil, winding it on a stick, and placing it in the middle of the hill of vines, so that the cloth shall be just above the surface. Still another correspondent, "Jno. F. McE.," highly recommends dusting the plants with powdered charcoal, which he says has always proved efficacious.

Oil Soap for Cabbage Fleas.—A subscriber has tried this remedy the present season, and saved his plants, while his neighbors lost theirs, even when treated with lime and ashes. He ties the soap in a bag and presses out a little of it into a watering pot, thus avoiding the strings or undissolved portions often left when the crude soap is stirred into the water. The solution is then sprinkled over the plants occasionally, and the insects flee away to more palatable pasturage.

Turnips with Corn.—"Beginner," Berks Co., Pa. There is little or no danger of injury to the corn crop in sowing turnip seed among the rows, immediately after the last hoeing. The corn is so far advanced, and its roots so widely spread, that the little growth made by the turnips before the ears are filled, will scarcely be any impediment to the full development of the latter. The turnips will make the principal part of their growth

after the corn is cut and shocked, if that be done as soon as it is sufficiently ripe, and thus a second crop of considerable value for market or for feeding, may be raised at a trifling expense. The quick-growing varieties, as the Red Strap-leaf, Cow-Horn, etc., should be sown.

Hay Caps.—George K. Flower, Alleghany Co., Pa. These are made of thick cotton cloth, $1\frac{1}{2}$ to 2 yards square, roughly hemmed, and provided with loops at the corners for stakes, or with stones sewed into the corners, to hold them down. Manufacturers make them of cloth prepared so as to be nearly or quite waterproof, and also to resist mildew: these are undoubtedly preferable. They might be made large enough to shelter a stack, but thatching, if properly done, is a good protection, and much less expensive.

Renovating Poor Land.—"Amateur," Rockville, Conn. Poor sandy soil cannot be brought into good heart by cropping yearly with rye, cutting it high, and ploughing the stubble under. Sow it with rye and plenty of clover seed, and turn the clover under in the Spring following the rye harvest. Repeat this a few years, and the land will show an increase of capacity for yielding grain. A readier way, if practicable, is to give the field a thorough manuring, when any crop may be put in with fair prospect of a good return.

Depth for Covering Wheat.—R. McMinn, Vernon Co., Wis. Plowing in wheat is practised to some extent, but there is liability of covering it too deep. It should not be buried more than two inches, and we should usually prefer a depth of one to one and a half inches, depending much, however, on the quality of the land. A light sandy soil would admit of the seed being covered with safety at a greater depth than could be done without risk on clayey loam.

Changing Soils.—R. McMinn, Vernon Co., Wis. A sandy soil will be improved by the admixture of clay, and *vice versa* a heavy clay may be ameliorated by applying a dressing of sand. Usually this would be too expensive for application on a large scale; but where, as in your farm, sandy knolls are found surrounded by a clay bottom, an exchange would probably pay. It would be better to mingle the different soils well by plowing, than to open ditches and fill them as you propose.

Draining Uneven Land.—R. McMinn, Vernon Co., Wis. The texture of the soil, rather than the surface, determines where draining will be beneficial. A heavy clay, even upon a steep hill-side, would be benefited by draining, by freeing the ground of moisture, and by opening channels for the rain to pass off in long-continued storms, thus partially preventing the best soil at the surface being washed away.

Large Yield of Beets.—G. Hagenstein, Le Seur Co., Minn., writes that from the package of Mangel Wurzel seed received by him from the *Agriculturist* office last year, he raised seventy bushels of roots, on which his calves feasted during the Winter.

Weight of Hay in a Mow.—S. C. Pattee, writes to the Country Gentleman, that he bought a lot of hay, and after measuring it in the bay, it was weighed, and gave 570 cubic feet to a ton. It was cut late in the season and was not as heavy as it would have been if cut earlier.

Impure Water.—Rees R. Ellis, Armstrong Co., Pa., writes to the *Agriculturist* that after having worked a well fifty feet through solid rock, plenty of water was obtained, but of poor quality. It is described as being mixed with "motes;" some call it spa water. We cannot indicate a remedy without some more definite knowledge, but judge from the description that the water holds some mineral substances in solution. If this be the case, there is no way to free it but by distillation. If the impurities were held by mechanical mixture, they could be removed by filtering. In such a location we should advise to abandon the use of well water, and provide a filtering cistern of the required capacity.

Detecting Water Courses.—Edward Frost, Lapeer Co., Mich. The only way by which to detect where water will probably be found by digging a short distance, is to observe the conformation of the surrounding country, the inclination of the strata, course of streams, and the locality of springs in the neighborhood. The use of a witch-hazel rod, or any other witching for this purpose, is pure nonsense, resorted to only by the ignorant and credulous. Springs may be struck by digging horizontally into a hill-side, as well as by going downward, in a proper location.

Line Fences.—J. J. Winaus, Luzerne Co., Pa. Of course it is the duty of your neighbor to make his share of the line fence cattle-proof, and if damage occurs to him, through his failure to do so, he must bear it. In this and some other States there are very properly laws by which a man may be compelled to keep his part of division fences in good repair, and we presume this is the case in Pennsylvania.

Pruning Young Trees.—C. J. Wilson, Oneida Co., N. Y. The best management is to nip superfluous shoots and shorten rampant branches while young and tender; then the use of the knife will seldom be needed. The present is a favorable time to take off branches that should be removed. Cut them smooth, and coat the wounds with grafting wax, or what is better, with gum shellac dissolved in alcohol, and they will soon heal over, and leave the tree uninjured.

The Ailanthus Tree, versus Insects.—W. J. B., Brooklyn, N. Y., writes to the *Agriculturist* that the maple, linden, willow and indeed almost all trees except the Ailanthus are in that city so infested with worms as to be a great nuisance; and hundreds of citizens after trying in vain to remedy the evil are cutting down the trees. Our correspondent states one fact coming under his observation, worthy of consideration. In several instances a tree whose foliage was preferred by the worms, standing between two of the Ailanthus species, remained unmoested. He recommends to set upon this hint, and plant the latter kind alternately with others which may be desired. If the fact noticed by him be general, the plan is worthy of adoption.

Raising Forest Trees.—John Waters, Dutchess Co., N. Y. It might be a paying investment to devote waste and rocky land to raising the more valuable kinds of timber, but on cleared land other crops give a quicker, and probably a better return. The experiment has hardly had a fair trial as yet, in this country, to enable one to judge of the actual profits of raising forest trees. We should be pleased to hear facts from any who have had experience.

Age of Fruit Trees.—Walter J. Evans, Benton Co., Iowa. The age fruit trees will attain and continue to produce, will depend greatly upon the treatment they receive. By the neglectful methods usually pursued, apple orchards generally become unproductive in from twenty to thirty years; but there are instances where apple and pear trees have continued vigorous for more than one hundred years. The actual limit of the life of trees can not be accurately stated; we know of no conclusive experiments made to ascertain the facts.

Cultivating Horse Radish.—F. E. Marlowe, Carroll Co., Ill. This plant like most others is greatly improved by careful cultivation. It delights in deep sandy soil enriched with plenty of manure. Specimens of roots two feet long, grown in almost pure sand which was yearly overflowed by a turbid stream, have been exhibited at the *Agriculturist* Office. In the vicinity of a large market like New York City, the crop commands a ready sale and is very profitable. Thousands of bottles are grated and put up here every year for supplying vessels, and shipping to other ports, and so great is the demand that dishonest parties adulterate the pure article largely with turnips.

Treatment of Rhubarb.—L. H. Warren, Orange Co., N. Y. This plant needs very rich ground, as it is a gross feeder. The stalks should not be pulled the first year after transplanting, nor too closely at any time. The season is prolonged by cutting out the seed stalk which grows up from the centre of the crown.

La Constante Strawberry.—Among the many sorts of strawberries exhibited at the *Agriculturist* Rooms, this promises remarkably well. It was shown by W. S. Carpenter, June 25th, in great perfection. It originated in Belgium, and is in high repute in that country, and also in France. Fruit large, conical, very regular, dark scarlet, or crimson color, flesh firm and of fine flavor. Flowers perfect. Its regular form, and fine bright color, make it a favorite late sort.

Cheap Fruit Boxes.—The call for a cheap box, which may be sold with the fruit, is being responded to in various quarters. The last noticed, are quart boxes made from a thick wood shaving, cut part way through at the corners, bent to a square form, and tacked. The bottom is coarse basket work made of splints, set $\frac{3}{4}$ inch from the bottom of the sides. They are manufactured by A. F. Newell, of Trumbull Co., O., for \$10 per 1000.

Annual Larkspurs.—D. P., Johnstown, N. Y. Both the tall branching, and the dwarf "Rocket"

are good, but the latter especially so. For the finest results, the seeds should be sown in September, and then the plants lightly covered in Winter. Early in the next season, and for a long time, they will display their double hyacinth-like flowers, blue, pink, white, pearl color, etc., and all very beautiful.

Kicking Cows.—A subscriber in Essex Co., N. Y., who has had a large experience with cows, and especially in breaking in heifers, says that gentleness and straps around the legs are the best things to use. He buckles the front foot upon the milking side, back upon the leg, and passes another strap around the two hind legs just at the hough joint, fastening the legs near together. In this position it is impossible for the animal to kick or step about; then, soothing words and gently rubbing the bag will soon take away the inclination to kick.

Cooking Food for Swine.—Wesley V. Houten, Suffolk Co., N. Y. It is generally believed that food is better fitted for fattening purposes by being cooked, but it is not certain that the advantage in this respect will repay the necessary outlay in fuel, labor, and time. Careful and extended experiments are needed to determine this point. The subject is important enough to warrant the trials necessary to decide the question.

Cover the Swill Tub.—Passing by a neighbor's sty the other day, we noticed five dead ducks, and upon asking the cause of their death, were told, they got into the swill tub and were drowned. Now though the duck is a good swimmer, it cannot make its way through, nor out of thick swill. We have frequently seen barn yard fowls, goslings, turkeys, and even pigs, pulled out of the swill tub in an exhausted state or already dead, and this last exhibition reminds us to say, keep the swill tub or barrel always covered, unless it is inaccessible to animals of all kinds.

Chaff for Feed.—S. B. Granger, Montgomery Co., Md. The chaff of wheat, oats, etc., wet and mixed with ground feed, is readily eaten by horses and cattle, and is probably as nutritious and healthful as cut straw or hay. Used in this way it will give a better article of manure than if thrown directly into the barnyard, as is usually practised.

Prevention of Smut.—George Larned, Calhoun Co., Ill. The following preparation may be relied on to prevent smut in wheat. Spread the grain rather thinly on the barn floor, and sprinkle it with human urine at the rate of three to four quarts to the bushel. Then add one to two quarts of fresh-slaked lime, and shovel the whole over until the kernels are uniformly coated. This should be done immediately before sowing, to prevent injuring the seed. This dressing will also give a quick and strong start to the young growth. A strong solution of blue vitriol (sulphate of copper) used in the same way, is efficacious in preventing smut, but the first named preparation is often available where the vitriol cannot be readily procured.

Potato Vines for Manure.—Henry Gerau, Lewis Co., N. Y. Potato vines contain a large amount of organic matter, valuable for plant food, and are worth saving for manure. Make a compost heap with the vines and muck, say a layer of the latter four to six inches thick, and a foot of the vines, and cover the whole with muck; or use common loam. The vines will speedily undergo active fermentation and decay, and the muck or soil will retain the gases passing from them.

Ashes for Manure.—William L. Smith, Orange Co., N. Y. Ashes are valuable as manure, in some degree on account of the ingredients which they contain, but without doubt also because of their action upon vegetable matter in the soil. They hasten its decomposition, and set free the elements which go to nourish the plants. Unleached ashes are of course preferable, as containing the most alkali, which is the active principle in their composition, but leached ashes have much value. They form an excellent addition to the compost heap in which muck is used.

Destroying Weed Seeds.—E. H. Parsons, Williams Co., O. The seeds of weeds thrown into a compost heap will lose their vegetating power if the manure ferments with sufficient thoroughness. There is danger however, that many seeds near the outside of the pile will be unaffected, and be ready to grow where they scattered with the manure. It is safest to burn all weeds the seeds of which are near maturity.

N. J. State Entomologist.—Dr. I. P. Trimble, of Newark, has recently been appointed entomologist to the New-Jersey State Agricultural Society.

Transporting Bees.—L. G. Comstock, La Fayette Co., Mo. Where bees are to be sent a great distance, ample openings for ventilation at the top and bottom of the hive are required. These may be covered with a wire cloth, which will retain the bees, and not impede the circulation of air. A very good arrangement was described and illustrated in the *American Agriculturist*, Vol. xix, page 76, (March, 1860.)

To Test Eggs.—L. A. Waters, Madison Co., Iowa. The most expeditious way we know, and which is generally practised by large dealers in this City, is to hold them between the eye and a lighted lamp or candle. If the egg is good, the light will shine through with a reddish glow, but if it be injured by incubation or from long keeping, it will be opaque or dark. This can be more readily discerned by placing the egg in a paper or other tube and looking through it, or by partially enclosing it in the hand. With a little practice, a person will thus examine a large number of eggs in a very short time.

Preserving Eggs.—A. M. Ward, Hartford Co., Conn., writes that after having tested a large number of directions for keeping eggs, he has adopted a plan recommended some years since in the *Agriculturist*, viz.: to place them upright in holes bored in shelves, and keep them in a cool dry place. This he says is satisfactory.

Milky Eggs.—C. S. D., Westchester Co., N. Y., writes that eggs from his hens taken when quite fresh, and boiled, do not fully coagulate, but part of the white is of the appearance and consistence of milk. We have never observed any thing of this sort, and can give no explanation of the phenomenon.

Trees for Transplanting.—D. Wells, Lewis Co., N. Y. Trees raised in the nursery are usually preferable to those growing in the woods, for transplanting. The latter have usually a tall spindling growth, which is in most cases undesirable. If wild saplings are taken, choose those which have grown in open fields or on the edge of the forest.

Bearing Year of Apple Trees.—Charles Snow, Cumberland Co., N. J. It is supposed that some apple-trees bear only during alternate years, because of some peculiarity which renders them unable to store up sufficient fruit-making material in a single year. Whether this attempted explanation be correct or not, it has been proved that by liberal manuring and keeping the ground loose by cultivation, the habit may be broken up and a crop gathered annually.

Cherry Trees Splitting.—J. H. Mead, Warren Co., O. A too rapid growth of wood upon very rich soil is said to often cause the wood of cherry trees to split. One who had lost many trees in this way says, that the difficulty was entirely remedied in his case by removing the highly manured soil about the trees, and supplying its place with that of poorer quality.

Time for Setting Cranberries.—W. L. Maxwell, Ontario Co., N. Y. Experienced growers say that cranberry plants may be set during any month in the year when the ground is not frozen; we should however prefer May or October, as then they are in a state of rest, and less liable to injury by wilting. The plant is very hardy, and with a little precaution will grow at almost any time. The upland variety, about which you inquire, is cultivated to some extent, but we are not prepared to endorse all the claims made for it by those having plants for sale.

California Wine, Wool and Stock Journal.—This monthly journal devoted to the above subjects has reached its sixth number. It is, of course, especially suited to California, but its articles on wine making by Mr. Haraszthy will be of value wherever grapes are converted into wine. The typographical appearance of the journal is fine. We wish it all success.

The Apple Worm.—Francis Thomas, LaSalle Co., Ill. This insect appears in the Spring as a miller, and deposits its eggs in the calyx or eye of the young fruit. From the egg, a worm or larva is hatched, which eats its way to the centre of the fruit, causing it to fall to the ground prematurely. If left there undisturbed, the larva will undergo its change to chrysalis and winged insect, and be ready next Spring to multiply its progeny. A few swine should have the range of the orchard to gather the blasted fruit, and thus keep the insect in check.

Remedy for Borers.—W. H. Williams, Queens Co., N. Y. We know of no outward application

to the trunks of trees that will prevent the borer from committing its depredations, where they have once effected a lodgement. Resort must be had to cutting in until the 'varmint' is reached, and extruding him. A sharp wire thrust into the holes will reach those that have not wormed too crooked a track.

Ripening Tomatoes Early.—R. S. Winsted, Delaware Co., Iowa. The maturity of tomatoes may be hastened by pinching off all new growth of the vine after a fair amount of fruit is set. The strength of the plant will then go to the growth of the tomatoes. Treated in this way the plants may be set nearer together than when they are allowed to run at will, and thus nearly as much early fruit may be realized from a given area as would naturally have been produced without pruning. The size of the tomatoes will also be improved.

Hardiness of the Tritoma.—This half-hardy plant can be wintered out of doors easily, by covering it late in the Fall with leaves or other porous litter, and then throwing over it a few inches of soil. Uncover gradually in the Spring; by the 5th of May, all covering may be removed. Yet, if one thinks it less trouble to do so, he can lift his plants in the Fall, and bury the roots in old boxes, and keep them in the cellar. We have tried both ways successfully.

Wax Flowers.—Generally we dislike to see any attempts to imitate flowers, as the artificial ones usually fall so far short of the natural that they are mere caricatures. We must confess that our prejudices have been lessened by the specimens placed on our table by Miss Van Bergh, No. 1143 Broadway, N. Y., which represent not only the shape but delicate texture and grace of the real flowers. Such a difficult flower as the Mignonne is represented with remarkable fidelity.

The Way the Wind Blows.—S. Ransom, Ashtabula Co., O., kept a series of weather notes during the year 1862, from which it appears the wind blew from the North 107 days, from the East 102 days, from the South 17 days, and from the West 9 days. There were 133 clear days, 91 cloudy, and the same number of rainy days. It snowed 50 days, making 31 days of good sleighing. The coldest weather was the 14th of February when the mercury fell to 19° below zero, and rose to 99° above on the 11th of August.

Kilns for Burning Charcoal.—Walter S. Williams, Rensselaer Co., N. Y. These are used in some places, especially in connection with iron furnaces where large quantities of charcoal are consumed. For manufacturing on a large scale they are doubtless most economical. The walls are built of brick about nine feet high, and arched over with the same material. Occasional openings the size of a brick are left for ventilation. They are built to contain from forty to fifty cords of wood, which yields about fifty bushels per cord.

Value of Zinc Paint.—W. W. Farwell, Oneida Co., N. Y. This article is superior for painting all surfaces exposed to the action of gas from coal fires, or from decaying matters, as in cellars, privies, etc. It is not affected by sulphuretted hydrogen gas, which causes white lead paint to turn dark. It costs no more than lead paint, as the same weight, though of greater price, will cover a larger surface.

Sugar Prospects in Illinois.—In addition to the unusual breadth of sorghum sown in this state we learn that the sugar beet has been largely planted. We hear that Prof. Mot, an account of whose experiments were given in the *March Agriculturist*, expects to make this Fall 300,000 pounds of sugar from the beets raised by himself and the neighbors whom he has interested in the culture. Success to him.

Mother's Journal.—"E. A." This is a very excellent monthly edited by Mrs. Caroline O. Hixcox, 335 Broadway, New-York. \$1 a year. Its articles are judicious and instructive—not of the sentimental class so common in Journals of the kind.

A Ladies Magazine.—"Sarah." Minnesota. We know of nothing else approaching so near what you inquire for, as the "*Ladies Repository*" published by Poe & Hitchcock, Cincinnati, Ohio, at \$2.50 a year. It is every way a first class magazine, with fine original steel engravings, and full of good sterling common sense articles, interesting and instructive—not to grave nor too gay. It has an immense circulation already, but may well be introduced into any other family, where it is not yet known. The true lady, married or unmarried, will find it both entertaining and useful.

Horses Wanted.—Walter Miller, Harrison Co., O. The demand for good horses is at present far beyond the supply, and promises to remain so for several years to come. The country has been swept of its surplus, to supply the requirements of the army, and many more will be needed in this service. There is also a continued call and ready sale for extra animals at extra prices. We believe raising colts will be found one of the most profitable branches of farming for a few years.

Salting Cows.—"Martha," Saratoga Co., N. Y. We cannot say positively that neglect to salt cows will detract from the quality of butter, or prevent its being easily gathered after churning; but where all requisites for good butter, except this, have been observed, and the butter fails to give satisfaction, it is strong evidence that salt is wanted. Perhaps some of our readers can give facts from their experience bearing on this point. At any rate, it is easy to salt the cows regularly, and note whether any improvement takes place. If the "good man" fails to do it, take a walk into the pasture at convenient seasons, and give the stock a treat. They will soon learn to welcome you.

Beef Brine for Warts.—James Warden, Baltimore Co., Md., writes to the *Agriculturist* that he has removed warts from several horses by washing the part twice a day with beef brine until the excrescence disappeared, which he says took place in a few days.

Selection of Seed Wheat.—G. H. Wilson, Iowa Co., Iowa. In selecting wheat for seed, if it is to be purchased out of your own immediate neighborhood, endeavor to secure a kind which has succeeded in a climate and soil similar to your own. It will not be amiss to experiment on a small scale with varieties of which little can be certainly known, but for the main crop only that should be sown about whose good qualities and suitability for the location there are no reasonable doubts. See that all seed is fully ripe and plump, entirely free from the seeds of weeds, and not more than two years old; one year, or less, is preferable. Sow only one variety on the same ground.

Wheat Crop in Indiana.—Ellis Jones, of Marion Co., reports that the crops in his vicinity will average well. He sends a splendid head from a neighbors field where the crop will yield not less than 25 to 30 bushels to the acre.

Greasing Hens.—John Bright, of Cumberland Co., N. J., says that it does not answer to grease hens with him, as no chickens are hatched after it if the hens are greased ever so little.

Kerosene for Curculio.—S. D. Palmer of Lenawee Co., Mich., says that he followed the suggestions of Mr. Richardson, of Norfolk Co., Mass., and used Kerosene oil to prevent the attacks of curculio and thereby killed four fine plum trees. Will Mr. Richardson inform us if the plan still succeeds with him?

Urine for Ants.—O. Ursenbach of Utah informs us that he has for the last two years successfully destroyed ants by means of urine. Early in the morning he removes a little of the earth from over the nest and empties the contents of a chamber vessel upon it. He finds that one application is generally sufficient.

Gooseberry and Currant Worm.—S. H. Murray of Maine, says, he has found nothing to answer but hand picking. He would like to know how to kill them. Can any one of our readers help him? One of our exchanges has a communication from a gentleman who found salt a complete remedy, but added in a postscript, that it killed the bushes too.

Hemp and Caterpillars.—F. W. Peterman, of Kentucky, advises those who are troubled with caterpillars on their cabbages to sow hemp between the rows. He says that they do not like the odor of the hemp, and leave. What does Mr. P. do with his hemp when it grows tall enough to shade the cabbages?

Spare the Snakes.—Not the Copperheads, rattlesnakes, nor other venomous reptiles, but the inoffensive striped snake, black snake, etc., which live mainly upon insects and worms, and which are true friends, although disguised in a form against which there is almost universal prejudice. They certainly are more beautiful and graceful than the toad, which is now a universal favorite among gardeners.

Quince Stocks.—Ignoramus is informed that the Angers quince is preferred to the common variety for dwarfs, as it is a much freer grower. The few cases

in which we have seen the common quince used were not very successful.

The Grape Vine.—Mrs. Bradford, Lynn, Mass. The new shoot which started from below will be precisely the same kind of grape as if it came from a bud above ground. It is only with grafted fruits that a different kind may be looked for. We suppose that the celery alluded to is the result of high culture.

The Cut-leaved Blackberry.—We find very different opinions regarding this variety. Some, whose judgment we value, speak favorably of it. A. W. Corson of Penn., writes us that he planted it about the year 1844 and it has proved worthless; he does not recollect to have seen one common sized berry on it. A neighbor of ours offered last Spring to give it away to those who would take it out of his grounds.

Cleaning Fruit Bottles.—Maggie H. Hagerly wishes to know if the cement can be removed from fruit jars, that have been once used, by any other method than the slow one of scraping them. We should suppose that if put into strong lye or potash water, the cement would be dissolved off, but we have never tried it.

Large Thread Factory.—A Company at Willimantic, Conn., are about erecting an immense building for the manufacture of linen thread. It will be 640 feet long, 170 feet wide, and run 20,000 spindles. It is said that when completed, this will be the largest thread mill in the world.

Ground-Glass Shades.—"E. S. D.," of Phoenixville, Pa., asks "would a room receive less light from a lamp on which a ground-glass chimney or globe is used than when the chimney or globe is unground or plain?" We believe that the amount of light would be the same in both cases, but in coming through the ground glass, the light is dispersed in all directions, and hence it appears to be lessened in quantity.

Gas Tar for Paint.—J. J. Malcolm, Van Buren Co., Mich. In localities where this substance can be readily obtained, it forms a cheap and excellent paint for woodwork exposed to the weather. It is not desirable for houses or front fences, but for barns, sheds, rough fences, tools, etc., it is just the thing. It acts as an excellent preservative by excluding air and moisture from the wood, and also by its chemical effect. Its unpleasant smell will pass away in a few days after application.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed upon our tables since our last report.

FRUITS, ETC. Strawberries:—Prince Albert, and a collection of seedlings from England, shown by Robert Wade, Troy, N. Y. Austin, 126 berries on one plant set out from a runner in 1862; G. K. Riker, Stamford, Conn. Union; S. R. Trembley, Bergen Point, N. J. Chance Seedling, quite white, believed to be from Wilson's; Wm. F. Heins, Morrisania, N. Y. Specimens for name; Richard Lawrence, Yonkers, N. Y. Seedling from Black Prince and Hovey; Mrs. C. Swazy, Hope, N. J. White Alpine; George Kellogg, New Canaan, Conn. La Constante, very fine, Bonte St. Julien, Russell's Prolific, Triomphe de Gand, Empress Eugenie, Marguerite, Victoria, Austin, Duc de Malakoff, Brooklyn Scarlet; Wm. S. Carpenter, Rye, N. Y. Cherries:—Fine Bigarreau Doulin; C. Marc, Astoria, N. Y. Black Eagle; George A. Shelton, Newark, N. J. Specimen for name; E. Williams, Mt. Clair, N. J. New Jerusalem; Dr. I. P. Trimble, Newark, N. J. Ox Heart, 18 on one spur; A. Granger, Washington Heights, N. Y. Large Red Prol; Prince & Co., Flushing, N. Y. Gooseberries:—Union and English; D. H. Barnes, Pokeysie, N. Y. Currants:—Red Dutch, White Dutch, Cherry, White Grape, Victoria, Prince Albert, Versailles; E. Williams, Mt. Clair, N. J. Provence and Grape (white varieties), and Cherry; W. S. Carpenter, N. Y. Naples (black); E. C. Wheeler, West Orange, N. J. Raspberries:—Belle de Fontenay, Fastloff, Hudson River Antwerp, Orange, American White Cap, Black Cap, Franconia, White Antwerp; Mr. E. Williams, Mt. Clair, N. J. Mulberries:—S. Tuttle, New-Haven, Conn.

FLOWERS:—Basket Cut Flowers; Thomas Cavanach, Brooklyn, N. Y. Magnolia grandiflora; Wm. Lillenthal, Yonkers, N. Y. Fine collection of Cut Roses and other flowers; Wm. Chorton, Staten Island, N. Y. Bouquet of Flowers; W. E. Meserau, N. J. Cut Flowers; John Drummond, gardener to Mrs. James Strong, Newtown, N. Y. Night blooming Cereus, and

Magnolia macrophylla; A. P. Cummings, New-York Arum Drauculus, and Cut Flowers; H. T. Haviland, Brooklyn, N. Y. Collection of flowers in pots; O. Judd, Flushing, N. Y. Splendid collection of Auriculas and Sweet Williams; B. K. Bliss, Springfield, Mass. Hydrangea Japonica, very beautiful; Wm. Cortelyou, Staten Island, N. Y. Perpetual Rose, one cluster with 131 blooms; A. P. Cummings, New-York. Yuccas in bloom, and Cut Flowers; Thomas Cavanach, Brooklyn, N. Y. Brugmansia, fine bloom; Mr. James, Brooklyn, N. Y. Gloxinias in variety; A. Janes, Morrisania, N. Y. Collection of Carnations and Picotees; Wm. Wilson, Florist, Astoria, N. Y. Bloom of Pancratium; Mrs. Allston, Brooklyn, N. Y. Fine collection of ornamental plants; J. S. Barnes, Port Richmond, N. Y.

MISCELLANEOUS:—Large egg weighing 4 oz., Levi Springsteen, Jr., New-York. Leaves from the Sago Palm Tree; D. Cordier, College Point, N. Y. Green Corn fit for the table, July 11th; G. M. Usher, Port Richmond, N. Y. Wax model of Newtown Pippin; Mrs. H. M. De Wolfe, 923 Broadway, New-York. Golden Summer Crook-necked Squash; J. McLane, Monmouth, New-Jersey.

Preparations for the Great Fair

Oliver Hoyt, Esq. who is travelling in Europe writes to the "Methodist," concerning the International Exhibition to be held at Hamburg, Germany, the present season, "The fair is to be on a grand scale: the ground occupied is eighty one acres, of which more than one third is covered by sheds. At the entrance to the ground there is erected an arch, which will be decorated with all the flags of Europe, and among them the glorious Stars and Stripes of America will be prominent. The entries of live stock have already reached four thousand one hun-

dred and sixty six. Of these fifteen are Arabian horses of the finest blood. Of course, our country will not send horses or cattle four thousand miles across the seas, but we expect a very good exhibition of farming utensils, and believe we shall excel all other nations in this department. I have learned in relation to American implements, a fact worth noting. A Russian diplomatist, high in official position, wrote a letter to one of the managers of the Fair, wishing to know if America would be represented, saying if she were not he would not attend. On being informed that America would be represented, he replied that he would attend, and twenty or thirty Russian nobleman with him. Similar inquiries have been made from different parts of Germany."

The New Mail Law.

On the 1st of July a new act of Congress went into effect, which makes several changes in our rates of postage. For the convenience of our readers we note the provisions of most interest to them.

Postage on letters weighing half an ounce or less is three cents to any part of the United States. Formerly letters to California and other Pacific States were 10 cents. Letters delivered from the office where they are mailed pay two cents. In towns where there are letter-carriers they make no charge for delivery.

Postage on newspapers must be paid in advance. The postage on the *Agriculturist* is now twelve cents a year, to be paid in advance at the office where it is delivered.

The postage to the Canada line has to be paid here, and the subscription price of the *Agriculturist* to be sent to our Canadian friends, will be \$1 12.

Newspapers sent by mail to those who are not subscribers must have a two-cent stamp, if not over 4 ounces in weight, and the same for each additional 4 ounces.

Books by mail must pay 4 cents for any weight not over 4 ounces, and 4 cents for each additional 4 ounces, or part of the same. No parcel weighing over 4 pounds can be sent by mail. Postage on books to California is the same as to any part of the United States.

The franking privilege has been greatly restricted. We are requested by the Commissioner of Agriculture to say that the right to send seeds, cuttings, etc., from that Department, has not been abridged, but that they can still frank parcels weighing not over 32 ounces.

What of the Future?

In forming an opinion as to the probable prices for the produce of this year, there must be taken into account some elements not usually affecting the course of trade. First there is the continuation of the war, the effect of which has been largely felt, and upon which very materially depends the state of the markets. The present prospects are full of hope for its successful termination at no distant day. The recent glorious victories have so restored confidence, that gold, which at one time stood at 170 and over, has fallen to 125, and few are eager to speculate in it at that figure. The effect of this will, of course, be to reduce the price of wheat, but with it other commodities to be purchased by the farmer must fall in equal ratio, which will compensate for the apparent loss. As the rate of exchange with

foreign countries follows the fluctuations in the precious metals, all imported goods will be subject to a falling off in market value, so that the diminution in this direction need not be counted as unfavorable, but rather the contrary. The accumulated stocks of foreign wares will be rapidly pressed upon the markets, and ensuing competition must still further depress the figures at which they are held.

From all the information we have received, we judge the wheat crop to be about an average one, and as a large breadth was sown, there is prospect of a good supply. The harvests abroad appear to be an improvement upon those of the previous two years, which will have the tendency to somewhat lessen the exportation. But the political aspects of Europe are such that the whole course of foreign trade may be entirely revolutionized within a few months, or even weeks. Should a general war convulse the Continent, the demand for breadstuffs from this side the water must greatly increase before the close of the year, and everything must go up with rapidity. The uncertain feeling on this subject even now influences the general market.

From a survey of the whole field it would appear that there will be at least remunerative if not high prices for what provisions the farmer may have to sell. There is not, we judge, anything to favor holding on in anticipation of any great rise in value. Wool will probably continue firm, not perhaps maintaining the unprecedented rate it has attained during the year, but yielding returns that should satisfy wool-growers, except perhaps those who embarked in the business at the height of the tide, hoping to realize almost an independent fortune. The producer who so keeps his accounts that he can calculate at what figure he can afford to sell his commodities, and who, year by year, disposes of them when that figure is reached, will in the long run show a better balance-sheet than he who trusts to occasional sudden rise of prices to ensure him large profits.

What to Do with Money.

Not a few of our readers have during the past year or two accumulated more than is apparently wanted in their business. To many it is a somewhat perplexing inquiry how to bestow their goods. They desire that their surplus capital shall be safe, and that it shall yield a fair return for the investment. We have counselled, and still advise, that the Government securities now in the market are among the very best stocks. Their value enhances with every victory, and we rejoice that these are multiplying weekly. But there is danger that many will overlook investments nearer home that would be equally safe, and in the end more remunerative. It has been proved over and over again, that capital judiciously used in farming can be made to pay a percentage with which reasonable men will be abundantly satisfied. Indeed the want of sufficient means to properly improve the farm and bring it up to its best producing capacity, is the great hindrance to the advancement of thousands. They are barely able to make ends meet when interest day comes round, and are unable to drain, to subsoil, to manure, to build and fence, and thus from year to year the farm is at a stand still, if it be not running down. To such we repeat the advice repeatedly given in these columns, sell part of the farm and improve the remainder, and there will be more satisfaction in working, because of less embarrassment, and in the

end, greater profit. To those whose farms are already paid for, and who are so fortunate as to be inquiring what to do with their surplus capital, we say, spend it on the farm, if it be not already at the highest point of productiveness. Fifty dollars per acre spent in draining will often give an increased fertility to the soil equivalent to ten, or even twenty per cent on the amount expended. So of buildings for shelter, planting of orchards, and purchase of manure. Each for himself will be enabled to judge what is lacking to make his a first class farm.

Many capitalists have shown their foresight by seeking investments among the agricultural community, advancing funds to young men just starting in the world, for the purchase of farms, or to those desiring to improve the land already owned. Others have wisely purchased homes in the country, and deeded them to their wives, that something substantial may remain in case of reverses which often prostrate the most successful business men. Hundreds of these will in after years discover that this was wise, not only because it saved something from the wreck of their fortunes, but from finding in the peaceful occupations of intelligent husbandry a satisfaction never enjoyed in the whirl of the city, and more than this, a better atmosphere, moral as well as physical, for the education of their children. Many among our readers are of the mercantile and manufacturing classes, and they may well give this subject their careful thought. In the end, some of them will without doubt, thank the *Agriculturist* for having made these timely, practical suggestions.

Mallory and Sanford's Flax-Dressing Machine.

As the time is not far distant for gathering this crop, so important the present year, we are impelled to again call attention to the great improvement effected in the preparation of the fibre for market, effected by the use of this machine. We have watched the progress of the invention for several months past, and have been pleased to find our first opinion of its importance and excellence endorsed by many who have during this season purchased machines and had them in operation. Not only will this apparatus effect a large saving in time and material, but by its use, tangled flax straw, which has heretofore been counted only as so much waste, where flax was grown for the seed, can be brought to a marketable state, to be transported to the paper mills, and worked up, or to be manipulated by the manufacturers of flax cotton. We know of no invention recently introduced that bids fair to do more in cheapening paper stock, and also in reducing the price of textile fabrics. If the manufacture of flax cotton proves an ultimate success, of which there seems at present to be strong probability, it will be difficult to estimate the value of this flax-brake to the farming community. The hand-power machines recently manufactured by this firm will enable a single person to dress 600 lbs. of flax straw in a day easier than half that quantity could have been broken with the old-fashioned hand-brake. Whoever has this year engaged in flax culture, will do well to correspond with this firm in relation to their implement. Their advertisement will be found upon another column. We have no personal interest in this or any other machine, but we deem it a favor to the community to bring so useful an implement into general notice.

A New Potato Digger.

Whoever has dug potatoes with a hoe, fork, or hook, has doubtless wished that something might be invented which would dispense with this tedious and fatiguing labor. We have recently inspected a new machine which promises to effect as great a revolution in the potato field, as the mower and horse rake have accomplished in the hay field. The machine is the invention of S. B. Conover Esq., a well-known commission merchant in West Washington Market. Its construction and action will be readily understood by the help of the accompanying engravings. Fig. 1, gives a view of the machine at work, and fig. 2 represents a lengthwise section of it, the letters referring to the same parts in both figures.

A strong sifter or riddle, *C*, runs the whole length of the machine; this is made of iron rods and is in the shape of a half cylinder; it is placed in an inclined position and has a vibrating or shaking motion communicated to it by means of gearing on the wheel at *G*. At the lower end of the sifter is a strong wrought iron scoop or plow, *E*, with a point of such shape as to readily enter the earth and so arranged that it may be plunged into the soil at any required depth, or be lifted out of the way of stones, stumps, or other obstacles by moving the lever, *I*. Within the sifter there is a large screw, *D*, looking something like the screw of a steam propeller; this is made to revolve by means of the gearing at *H*. These are the essential parts of the machine: they are mounted upon a frame, *A*, which has two large wheels at the rear and two small forward wheels which move like castors, independently of each other, and facilitate the turning of the machine. When at work, the wheels go between the rows of potatoes, and the scoop enters the soil directly under the row to be dug. The forward movement of the team pushes the potatoes and soil together into the sifter, the vibratory motion of which causes the earth to shake out, while the blades of the screw are constantly pushing whatever

may be in contact with them towards the rear end of the machine. Between the shaking and the stirring by the screw, the potatoes are soon freed from the dirt and keep travelling upward. At *E'*, the grating is sufficiently coarse to allow the small potatoes to drop through, and the large potatoes pass on and fall out farther on. The large and small potatoes are received in separate boxes which have hinged bottoms opening downward and so connected with the lever, *F*, that either box can be emptied at pleasure. The potatoes are delivered in assorted heaps, making the after work of picking up comparatively easy. Weeds and tops will be pushed out at the rear end of the sifter by the action of the screw. The soil will be left by the machine in excellent condition for the succeeding crop. We have seen a full sized machine, and although we have not witnessed its operation in the field, we can see no reason why it should not realize the hopes of the inventor. It has been suggested that this machine might also be used for the purpose of clearing land of small stones near the surface. Though the inventor did not have this object in view we think that it might be effective on certain soils. The machine we saw is well made and so simple in all its parts, as not to be liable to get out of order. If his invention will successfully substitute the work of animals for human labor in harvesting the potato crop, Mr. Conover will receive the grateful thanks of many members of the agricultural community.

The War and Agricultural Implements.

Dealers in agricultural implements report that the demand for labor saving machines during the present season has been altogether unprecedented. The manufactories of mowers and reapers, horse rakes and pitchforks, etc., although worked to their utmost capacity, have been unable to fully meet the orders. This has of course resulted in a large degree from the scarcity of laborers caused by the transferring of so many men to the field where other harvests than those of agriculture are being reaped. But it is also due, in some measure, to the influence of the agricultural press, which has for years been educating the farming community to the practicability of substituting animal and mechanical power for hand labor. This fact is one of the compensations of the war, and no slight one either. Its influence will be felt long after peace shall have called the absent laborers to their homes. It is, in fact, an emancipation of thousands of men from the necessity of severe toil; an emancipation which furnishes no elements for political agitation, but which

is none the less noteworthy. No man will willingly return to the old routine of muscule work, after having once enjoyed the comparative ease in haying time, bestowed by a good mower. One effect of this release of so many laborers will be to allow the cultivation of a much larger area of land. The Great West already owes much to the successful introduction of mechanical contrivances into agriculture, and its fertile prairies will ere long receive still larger accessions from this cause. The influence of this change will also be widely felt in the number of young men willing to follow the profession of farming, now that so much of exhausting labor

Fig. 2.—SECTIONAL VIEW OF THE DIGGER.

is relieved. The work of the farmer will take rank above mere manual labor, which will always hold a lower place than the exercise of skill. Although this may appear of little account in any particular neighborhood, in the aggregate, the results will be of great importance. Agriculture needs the brain work of many a man whose muscles are not strong enough to handle the scythe, and not a few such will be added to the ranks by the general introduction of farming by machinery.

Blooded Stock vs. Native.

A subscriber asks the pertinent question, will a blooded or grade animal sell for more in the cattle market than one of the same weight of native stock? We answer yes, usually, for the reason that high-bred cattle have their weight developed on desirable points. Bones are valuable for many purposes, but no butcher will pay 9 to 12 cents per pound for them, when he can obtain an equal amount of good meat for the same price. Native animals occasionally show great symmetry of form, well developed muscle, and meat laid on where the butcher and epicure like to find it. In such cases the market value of the animal will not differ materially from that of one having a long good pedigree. Usually, however, it is found that native breeds give more of offal and coarse meat, than those bred for generations back with a view to fitting them for the shambles, and hence their value for slaughtering decreases correspondingly. It should be constantly kept in mind, that it is not the peculiar excellence of single animals that wholly determines their value upon the farm. A perfectly well-formed native cow yielding a generous supply of milk, is justly prized for her individual qualities; but the owner can not, with any degree of certainty, expect her good qualities to be transmitted to the next generation. Of course her calf will be more likely to prove good than one from an ill-favored dam, but the deficiencies of her ancestors may crop out in an unlooked-for degree, and render the progeny comparatively worthless as a breeder. It requires many years of careful management to fix the qualities of a breed of animals, so that they shall be repeated in the progeny. There must be a counter-balancing of points, and overcoming of deficiencies, by proper selection of sire and dam, for many successive generations. Unquestionably this may be done by starting with a promising native pair, and continuing to breed sufficiently long with reference to the development of desirable points. But few are found possessed of sufficient means, time, patience, and perseverance, to carry the process to a successful termination. A few have done so in other countries, especially in England, and the world is sharing the benefit of their endeavors. Again, even supposing success attainable by starting with native animals, it seems more feasible to begin with animals already possessing fixed qualities of excellence, and to super-add to these, by proper breeding, whatever may be wanting. Intelligent cattle raisers are pursuing this course, and already this country can furnish no mean show of blooded stock compared with that of any other land. To every farmer who proposes to raise but a single calf, we would say secure the services of the best blooded bull attainable, and continue to do so; in ten years you will find your account in it.

Importation of Wool—A Hint to Sheep Raisers.

It is a fact worthy of note that while the increased demand for the sorts of wool needed for broadcloths, cassimeres, etc., is being partially met by increased production, as yet little has been done to furnish supplies of the staple required in goods substituted for cotton; that is for the warps of worsteds, delaines, etc. The wool needed for this use is that which will make the smallest and strongest thread with the least nap from the smallest amount of stock. This is furnished in the greatest excellence by the

Leicester, Cotswold, and kindred breeds, and as comparatively very few of these sheep are raised in this country, the great bulk of wool needed for manufacturing purposes here, must be imported. Accordingly it is found that the importations during the present year have by far exceeded those of any previous period. The amount received during the past six months has very nearly if not quite equalled the whole quantity imported in 1862, and is greater than that brought in during both 1860 and 1861. But owing to the demand upon the other side of the Atlantic for a similar article, the price has advanced to an unprecedented figure, and such wool now commands, and must for some time continue to bring a price far beyond its actual relative worth as compared with wool of finer staple. In other words, a larger amount of money can be realized for wool by investment in these breeds of sheep. Now it behooves American farmers to reap a share of the advantages thus offered. Heretofore, the raising of the coarser bodied sheep has been advocated on the ground of producing superior weight and quality of mutton, and the advantage, if any, in this respect, is not less now than formerly, as any one will find who indulges in the luxury of this meat at present prices. The matter is worth thoroughly looking into by those who are about stocking their farms with sheep. Some enterprising men will reap a good return from importing improved flocks of these breeds, and we shall be pleased to chronicle their success in the *Agriculturist*.

WOOL IN PENNSYLVANIA.—A number of wool growers in Alleghany and Washington Counties, Pa., at a recent meeting, resolved to hold their wool at \$1 per pound until there is a change in the prices of cotton and woolen goods. The wool growers of Western Pennsylvania, have been called to meet in convention to consider the matter. Other events of greater importance will probably prevent their assembling for some little time at least.

Proper Depth for Manuring.

The Annual Report of the Secretary of the Massachusetts State Board of Agriculture, Charles L. Flint Esq., for the year 1862, contains, among much other valuable matter, the record of a most important and interesting series of experiments to determine the best depth for applying manures. The trials were made pursuant to premiums offered by the several Agricultural Societies receiving bounty from the State, and in accordance with the direction of the State Board of Agriculture. The following instructions were prescribed for experimenters: "Select a level piece of land of any convenient size, from twenty square rods up to as many acres or more, which should be as nearly equal in character and conditions as possible. Divide it into equal parts, numbering them 1, 2, 3, 4, 5, for a rotation of three years.

"Divide the manure which it is proposed to apply, and which should be of a uniform character, into four equal parts. At the time of first plowing in the Spring, spread evenly one fourth of the manure upon plot No. 1, and then plow the whole field of an equal depth. Apply another fourth part of the manure to plot No. 2, and then cross-plow the whole field to about half the depth of the first plowing. Spread another fourth of the manure upon plot No. 3, and harrow or cultivate the whole field; after which sow or plant the whole evenly with any

crop preferred. Finally, spread the remaining quarter part of the manure upon plot No. 4.

"Observe that by pursuing this course, each of the five lots will receive equally, a deep plowing and a harrowing, or cultivating; the only difference in them being, that in No. 1, the manure is buried deep, in No. 2, shallow, in No. 3, buried only slightly, but coated with loam, and in No. 4, exposed upon the surface, while No. 5, gets no manure. The manure is to be spread broadcast and as evenly as possible. The after cultivation should be the same on each of the lots, and the harvest of each should take place at the same time."

Fourteen experiments were carried through the three years of 1860, 1861, 1862, according to the above directions, and the details are given in full in the Secretary's Report. They present many items of importance, but from various causes can only be deemed as approximating to a decision of the matter in question. The summary of the different results shows that manure buried deeply gave the best returns in two instances; placed at a medium depth (by the cross-plowing) in six cases; when harrowed in, in four, and when left on the surface in two of the experiments. Taking the retentive soils by themselves, deep plowing of manure gave the greatest result in one case, shallow plowing in five, harrowing in three, and surface application in two. The light soils yielded the best returns from one of each of the several applications, except where applied on the surface.

The number of experiments was too limited to give a satisfactory decision of the question. Different crops were also cultivated by several of the experimenters, and various kinds of manure were used, both of which particulars might, in some measure, vary the results. The influence of the weather, whether wet or dry, must also be taken into account. This was recorded in the above cases, but it will require a long term of years to decide how far this will affect the general result. On the whole, there is ground to recommend the use of manures at moderate depth, as at least the probabilities seem to be in favor of this course, and we have no better ground for deciding. If the subject now so well opened, be followed up, in time an authoritative rule may be established. Such efforts toward solving the practical problems of Agriculture are worthy of all commendation, and we trust that the above example may not be without effect upon kindred societies. The Department at Washington might, by entering upon a similar field of experiment, bestow a just return to the country for the generous support which has been accorded to it by the people.

For the American Agriculturist.

Digging Muck or Peat.

With all that has been said upon the value of this substance for manure, the last ten years, it is not half appreciated. The majority of our farmers have never used it, and few of them who use it, conduct their operations so carefully as to know how much it is worth. I am writing in sight of a clover field dressed with muck, which blossoms all over in praise of the article. Labin never sent out such perfume as comes up from this muck-plastered meadow. The general conviction is, that muck is good on hungry, gravelly soils, and loose sands. It is, for I have found it thus, and seen the results. It may not be known that it is also good on muck lands. That meadow now so luxuriant with clover, good for three tons to the

aere, is a reclaimed swamp, and the manure was simply dried muck and fish pomace at the rate of not over five dollars to the acre. We have repeatedly tried stable manure composted with muck, upon the same meadow, with similar results. The popular faith that it is best for gravelly soils, is undoubtedly correct, but it is about good enough, when composted, for even reclaimed muck swamps. And this fact is not without its analogies. It is well known, that soils made up in part from lime rock, are much benefitted by applications of lime; and granite soils which are supposed to be rich in potash from the decomposed feldspar, show at once the effects of wood ashes.

The muck is ameliorated by the manure or ashes with which we have mixed it, and it shows its good effects upon the grass in a powerful manner. After using muck for ten years and more, we should hardly know how to farm on old soils without it. The present is the best season in the whole year to dig it. The swamps are now, many of them, without water enough to be troublesome, and the water is so warm, that one can stand in it barefooted all day without danger of taking cold. Then the warm season is much the best for curing the muck. When thrown out upon the bank of a ditch, it is drained of its superfluous water at once, and is heated in the sun. The outside of the heap very soon becomes as dry as powder and much finer than common soil. In this dry condition it is benefitted by the fall rains and the winter frosts, if it lies on the bank, and still more benefitted, if it is carried to the yards and stables. It is one of the best deodorizers for sink drains, privy vaults, and barn cellars, and a farmer should always keep a good supply on hand, and, if possible, have it sheltered ready for use. There is a great difference in the value of muck, owing to the trees and shrubs from the decay of which it is composed. But the immediate effects of it upon crops is still more determined by the condition in which it is applied to land. This summer curing before it goes to the compost heap, or the stables, we regard as very important. Without attempting to account for the philosophy of the fact, it does undergo a very rapid change in hot weather, and becomes much more available for plant food in the compost heap. If it is to be in the compost heap six months or a year before using, the summer exposure is of less importance. Muck digging ought to have a regular place in the yearly routine of labor. On the whole we have never found any farm operation to pay quite so well.

CONNECTICUT.

How About the Compost Heap?

In this season when the garden is teeming with vegetation, are you accumulating materials to meet next year's demands? We all know in what request manure is in the Spring, and provisions should be made for it now. The garden furnishes a large amount of refuse matter which should go on to the compost heap. An occasional load of stable manure may be added, and alternate strata of green vegetable matter and manure may be built up throughout the season. Every privy should have its vault so arranged as to be perfectly accessible for removing or adding to its contents. An occasional addition of muck and plaster or copperas (sulphate of iron) will completely deodorize the contents and make a highly valuable fertilizer. Do not forget the hen house in the summer season. A few shovelfuls of soil will

make the hen roost more comfortable for its inmates and assist in forming a manure equal in value to guano. It is better to save and accumulate manures now, than to be short and obliged to buy when the need is felt next Spring.

Fish for Manure.

It is a query whether fish are turned to their greatest possible account as manure. It would seem that by good management they might be made to fertilize a large part of the barren sands which line the sea-shore. And what more just than that the sea should render back some of the fertility which has been washed into it from the land. As Prof. Johnson happily remarks, "Guano is an indirect contribution of the ocean to Agriculture. The sea-fowl manufacture it from the fish with which the sea is everywhere teeming."—Analysis shows that fish abound in nitrogenous and phosphatic elements; and experience shows that they are very useful in bringing up lands otherwise quite unfertile. Indeed, we have known farmers to cart them fifteen or twenty miles distant from tide water, and to find the labor remunerative. Yet the slovenly practice of spreading fish on the surface of land or imperfectly covering it for the benefit of growing crops, is one to be condemned. It is wasteful, and exceedingly offensive, if not unhealthy to all the region filled with the foul effluvia.

But fish, in a crude state, can not be handled or carried many days in warm weather; they soon corrupt. Some method must be devised for curing and putting them into some concentrated and portable form. This was done some years ago in France and in England, and an article was produced which was reported to be as valuable as guano. Not long after, a similar article was manufactured in this country, at New-Haven Conn., Bristol Rhode-Island, and in New-Jersey, which was styled "Fish Guano," and which has become popular with those who have used it. Of the precise mode of preparing it for market, we know only a little. The fish used for the purpose are chiefly the Moss Bunkers or Menhaden (*Clupea Menhaden*), which are boiled or steamed, and thus reduced to a soft mass of flesh and bones. This mass, we are told, is now "chemically treated," then dried, thoroughly baked, and ground to a coarse powder. Possibly, the "chemical treatment" is only the application of sulphuric acid. This makes a powerful fertilizer. Another and less potent agent is made by mixing the boiled fish with some absorbent, like dry peat or street sweepings, and then drying it. This has greater bulk, and is called "Fish Compost."

But where neither of these prepared fertilizers are in market and at a reasonable price, we would advise seaboard farmers to use all the fish they can get, in their own way. They can profitably be laid up with muck in heaps, to decay. A barrel of fish composted with muck or loam will make a rich dressing for any crop.

Lessons of the Drouth.

How often have farmers read of the importance of draining, deep plowing, thorough pulverization of the soil, and other elements of good husbandry! And they have said to themselves, this is very good theory, and it is very well for others to practise, but *my* and don't need such fussing over. Yet, almost every year, in time of drouth, we hear them wonder why

their corn rolls up its leaves so much worse than that of more careful farmers, and why most of their crops dry so badly in mid-summer. Has not this been the experience of some the present year? They complain bitterly of the season, of Providence, of everything except their own management. Now and then they visit other farms where the land is well drained, where sub-soil plows are owned and used, where the manure heap is constantly building and no part of it suffered to waste, and where all the farm implements are kept bright by use; and here they find the crops almost unaffected by drouth. Their eyes are opened a little, and they begin to see that there is something in thorough farming, possibly in book farming. We have no doubt that an inch or two deeper in plowing often repays the farmer a hundred or more dollars annually, in the crops saved from drouth, or increased in amount.

Corn Raising in Illinois.

In the June number of the *American Agriculturist*, page 173, I find an article on the cost of raising corn in Connecticut. The writer says he raised last year on twenty-three acres, 1000 bushels amounting at \$1 a bushel, to \$1000. The expenses according to his estimate were \$599.25, leaving a profit of \$400.75. He says at the close, "Let Western farmers beat it, if they can." I will give what it costs me to raise 24 acres, and farmers here say it is a fair estimate.

12 days Plowing land at \$2.....	\$24
2 days Marking at \$2.....	4
2 days Planting, man, boy and team, at \$2½.....	5
Seed Corn.....	2
3 days Harrowing Corn, at \$2.....	6
12 days Plowing Corn, at \$2½.....	30
Interest on Land.....	20
Total cost.....	\$91
By 1,440 bushels Corn, at 30c.....	\$432
Net profit on Crop.....	\$341

A man will plow two acres a day easily; and with the markers we have, will mark 12 acres. The planting is done with a machine—a man to drive and boy to drop. I estimate the wages of the man and team at \$2, and the boy at half a dollar. Twelve acres is the lowest number planted a day. The harrowing is done as soon as the corn comes up (the front tooth of the harrow being knocked out). No harrowing is done before, as the plowing leaves the ground in good order. Plow the corn four times with double shovel plows, one horse to each plow. I hire a man and a boy, and after paying the man and boy there is enough left of the \$30 to pay for the use of the team. I count 60 bushels to the acre; as once harrowing and four times plowing will make it, 80 being frequently raised. If corn is worth \$1 in Connecticut, it is certainly worth 30 cents here. I do not estimate the gathering, as it is not counted in the report from Connecticut. My corn is worth 40c. to me to feed, but I have put the value at the lowest figures—the estimated value in the article referred to was at the *highest*. The ground is rich enough without manuring, and hoeing does not pay here. Mr. Dickerman expends \$599.25 to make \$400.75. I use \$91 to make \$341, or \$485, if I count it at 40 cents, which would be right, if a dollar is right for him.

Mercer County, Ill.

H. S. SENTER.

TRUE NOBILITY.—The day laborer who earns, with horny hand and the sweat of his brow, coarse food for a wife and children whom he loves, is raised by this generous motive to true dignity; and though lacking the refinements of life, is a nobler being than he who thinks himself absolved by wealth from serving others.

Fig. 1.

A Cheap Poultry House.

A correspondent "Lex," contributes the accompanying description of his poultry house. "The building (Fig. 1) is 8 by 12 feet on the ground—the side walls 9 feet high to the eaves. A partition runs lengthwise through the middle, from the ground up to a floor which covers all the interior, at the height of 7 feet. Two doors in the gable end open, respectively, into the two rooms thus formed. There are two tiers of nests, containing ten in each, all of which are movable boxes or drawers, so placed as to slide freely through the partition, from one room into the other. The right hand, or "laying room," has an ordinary opening through which the hens have ready ingress and egress, but the "sitting room" is closed to all but the "sitting members" and their human visitors. In this room, supplies of food and water are constantly kept, accessible to the sitting hens. Above the floor, or in the second story, are the roosting poles, to which access is had from the outside, as represented in fig. 1. The sectional outline (fig. 2) will illustrate the interior construction.

Whenever a hen takes possession of a nest in the laying room, manifesting a disposition to sit, the requisite number of eggs are placed under her, and her nest is pushed through the partition into the sitting room. Here she finds herself in a state of contented seclusion for the term of incubation. No rash removal from the nest of her choice here disturbs her maternal calculations. No ambitious layer molests her peaceful possession. Does she desire refreshment, solid or fluid? She has only to hop down to the floor of her apartment, where her wants are speedily satisfied, without a tedious search over the barn-yard, involving much peril to her neglected charge. When other hens, by similar process, have become occupants of the same apartment, there is still but one hen to each nest therein, and though they may sometimes change about, no nest will ever be left unoccupied. When hatching occurs, the mother and brood being removed, the nest box is taken out into the yard, where the straw is fired with a match, and suffered to burn until the sides of the box are slightly charred. This destroys all vestiges of vermin, incipient or otherwise, and leaves the drawer to be re-placed in its proper position, sweet and clean for a new nest.

Of the roosting place above, with the intervening floor, it is sufficient to say that, while the lower apartments are free from the droppings and easily kept clean, an abundant supply of "guano" is furnished where it can be raked out by the bushel, from time to time, for use in the garden and elsewhere. Both sides are open the entire length of the building, and the

hens enter by steps provided for the purpose. I have just forty hens. They have thus far (June 1st) hatched out three hundred chickens, fifty turkeys, fifteen ducks, and five Guinea-fowls, besides keeping us furnished with plenty of fresh eggs for table use and cooking, for eleven in family. I shall be much disappointed if my hens do not raise, say from seven hundred to a thousand chickens ere the season closes. The number of hens and capacity of hen-house, as herein described, seem very suitably adapted to each other, since there has, all along, usually been about one half the number of nests employed in either apartment. I add nothing in this connection on the subject of raising chickens after they are

hatched, since I have merely followed the old beaten track, and sustained about the usual percentage of loss from barn-yard accidents, etc. I have had better success with poultry this season than any of my neighbors, and believe the results due to my hen-house. It may be that your Eastern readers with their superior appliances, will find little in it to commend. But I

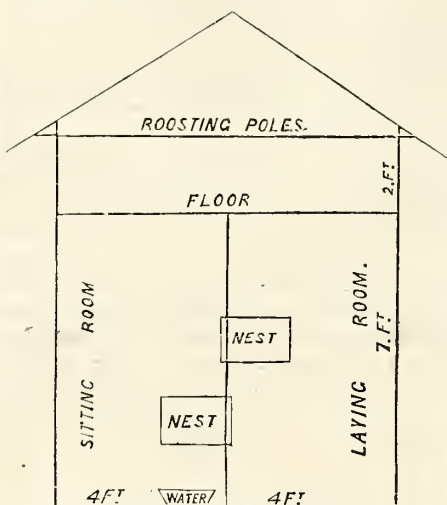

Fig. 2—SECTIONAL VIEW

write from the "Far West," where the numerous readers of the *Agriculturist* will find more interest in simplicity and cheapness of construction, with fair results, than in elaborate and expensive plans which promise fabulous profits."

Great International Wheat Show.

A great International Wheat Show will be held at Rochester, N. Y., September 8th, 9th, and 10th, under the auspices of the Monroe County Agricultural Society. The following premiums are offered:

For the Best 20 Bushels of White Winter Wheat.....	\$150 00
For the Second Best do do.....	75 00
For the Best 20 Bushels Red Winter Wheat.....	100 00
For the Second Best do do.....	50 00
For the Best 2 Bushels White Winter Wheat.....	50 00
For the Second Best do do.....	25 00
For the Best 2 Bushels Red Winter Wheat.....	40 00
For the Second Best do do.....	20 00
For the Best 2 Bushels Spring Wheat.....	20 00
For the Second Best do do.....	10 00

Competitors for these Prizes will be required to furnish samples of the wheat in the ear and with the straw attached, (say 50 ears of wheat and straw), also to furnish a written statement of the nature of the soil on which the wheat grew, method of cultivation, time of sowing, quantity of seed sown, manures (if any used,) and mode and time of application; also the time of ripening and harvesting, and the yield

per acre, with such other particulars as may be deemed of practical importance; also the name by which the variety is known in the locality where it was grown.

The Wheat must be one variety, pure and unmixed. The prize to be awarded to the actual grower of the wheat, and the wheat which takes a prize to be the property of the Society.

It is hoped that farmers in all sections of the United States and Canada, who have good samples of wheat, will compete for these Prizes. We have never yet had a good Wheat Show in the United States. It is highly important that the wheat growers of the country should meet together and compare samples of wheat raised in different sections. We understand that the money for these premiums has been raised by subscription, among the friends of Agriculture in Western New-York, and the time of holding the Fair has been fixed so as to enable farmers to purchase their seed from the wheat entered for competition. A change of seed is always desirable, and it is believed that all the wheat of good quality sent to the fair, will find purchasers at a high price. Full particulars of the Exhibition can be obtained by addressing the President of the Society, JOSEPH HARRIS, Editor of Genesee Farmer, Rochester, N. Y.

We take great pleasure in calling especial attention to this notice. A movement of this kind, if properly sustained by wheat growers, will be of incalculable benefit by bringing prominently before them the best varieties of this grain, and placing desirable sorts within their reach. The character of those having the enterprize in hand, is such that contributors may rely with the utmost confidence in their ability and fair dealing as judges. Let there be a full response from all parts of the country.

Chicken Pox.

A subscriber in New Brunswick, N. J., writes to the *Agriculturist* as follows: "I noticed a remark signed "J. E. R." in regard to the disease in his chickens called chicken pox. I had some 30 hens sick with it last year, and only lost two. I first washed their heads in warm water until their eyes were open, and then fed them with Indian meal boiled with powdered charcoal and flowers of sulphur—as strong as they would eat it. It is unnecessary to say my sick hens were separated from my well ones. Parties who keep a large stock of hens, said I should kill and eat the rest of mine before they were taken sick, as I could not get rid of the disease without a new stock and hen-house, but as my fowls were Spanish and Leghorns, I did not feel like killing them.

Notes on the Scale Louse and Cut Worm.

A correspondent of the *Agriculturist*, "J." writes as follows: "I have had scale lice completely cover the trunks and main branches of the *thriftiest* pear and apple trees, in two years. Thin soft soap (not suds) applied with a paint brush has never failed to kill them. They will turn black in a few days and finally drop off themselves. I have practised it for five years without a failure and with no injury to the trees. You recommend to "look after the cabbages early." Last season I did look after them early in the morning, and was accustomed to find 5 or 6 each day, (out of about 50 plants) eaten off. I used the "only remedy," searched for and found the rascal, but killing after he had destroyed the plant was but the satisfaction

of retaliation. I then, as an experiment, took 4 oz. aloes and dissolved in a gallon or two of water, and applied to the plants. I never lost a plant afterwards. This season I have done the same and have not lost a plant, except where I neglected to use the aloes water, and then out of 6 plants I lost 3 in one day. As soon as I had set new plants I applied aloes water, and the remedy thus far is effectual."

Talks About Weeds....III.

We supposed that our first article in the June *Agriculturist* was sufficiently explicit upon one point, i. e., that there are no specific preparations to kill particular weeds. Still as we are constantly receiving letters asking: "How shall I destroy Canada Thistle?" "What will kill Devil's Flax?" "What will remove Sweet Flag

Fig. 1.—RED ROOT OR PIG WEED.

safely be set down as a humbug. True, a destructive agent may be applied to an individual plant, as salt to thistles, the same as the surgeon may extirpate a wart by means of the knife or caustic, but this is a case of local treatment and cannot be applied to a whole field.

THE RED ROOT.—This has of late years become one of the pests of cultivated grounds. Its botanical name is *Amaranthus retroflexus*; it belongs to the Amaranth or true Pigweed family, which produces several troublesome weeds, but none so generally known as the one under consideration. (The plant most commonly called pigweed is *Chenopodium album*.) Figure 1 will give a good idea of the full grown plant. It is sometimes called "Pigweed," but the most common name is Red root, given on account of the red color of the root. The plant is distinguished by a great vigor and rapidity of growth, and if neglected for a short time, becomes so large as to resist the hoe and must be pulled by hand. Being an annual, a cut with the hoe destroys the plant, but the stock of seeds in the soil seems to be inexhaustable, and crop after crop will spring up through the season. The flower clusters are crowded with minute green flowers, each one of which produces a seed. From the prolific character of the plant it will be seen that a single one, if allowed to arrive at maturity, will furnish hundreds if not thousands of seeds. If the plant has flowered, it should not go into the compost heap, as, in common with many other plants, the stalk contains nutriment enough to perfect the seeds after it is cut off or pulled out of the ground. The plants, if they have flowered, should be dried and burned. Like all annual weeds this soon succumbs under careful cultivation. Another closely related plant the Thorny Amaranth (*Amaranthus spinosus*) is quite common in waste places about New-York and other sea-ports, but does not seem much disposed to extend into the country. It is certainly a vile weed and is readily distinguished by the sharp spines which are mixed in with the flower-clusters. This most unwelcome foreigner cannot be too carefully eradicated the moment it makes its appearance.

THISTLES.—Though we have some ten native and introduced species of thistle, there are only two which are very troublesome to the farmer, and these are foreigners. The common "Bull thistle," or "Michigan thistle," (*Cirsium lanceolatum*) as it is sometimes called, is the commonest of our thistles. It is readily known by its broad luxuriant foliage and its large heads, which are an inch or more in diameter. Though exceedingly troublesome, especially in grain fields, where its prickly leaves are a great annoyance to the binder, it is not difficult to exterminate. Being a biennial the root is readily pulled. During the first year the plant forms a broad tuft of leaves which lie close to the ground, and it does not attract much notice; the second year it throws up a large flowering stem from 2 to 3 feet high, and then becomes, from its very prickly leaves, a formidable enemy. During the first year of its growth a cut with the hoe, or a tablespoonful of salt applied to the crown of the plant, will destroy it. When it is allowed to run up to flower it should be pulled or cut as early as possible. The fruit, or seed as it is called, is provided with a copious down, and thousands of these little balloons with a seed attached may be seen floating upon the breeze from the field of some careless farmer to annoy his more thrifty neighbor. If a whole neighborhood can be aroused to exterminate this thistle, not only from the field but

from the road sides, they would soon be rid of the pest. This thistle is an exotic, but it seems to make itself perfectly at home in our cultivated fields, especially affecting the richest ground.

A.H.

Fig. 2.—CANADA THISTLE.

A far more troublesome plant is the Canada Thistle (*Cirsium arvense*) which is perhaps the worst weed with which the farmer has to contend. As other, comparatively harmless plants have been taken for this, we give a very good engraving of the upper part of a flowering plant. This differs from the common thistle in being a perennial; besides its strong roots, it throws out into the soil numerous strong root-stocks, or underground branches, and multiplies very much in the way described for the couch-grass in the last number. Running a plough or cultivator through a patch of it, instead of destroying it, only breaks up these root stocks, and they become many separate plants. This plant has two separate modes of propagation. The one is by its seeds, which are readily borne by the wind from place to place, and the other is by its underground stems, which from a partial warfare against them only flourish and multiply. When one Canada thistle appears upon the farm the war must begin. It is modest in its first appearance, presenting but a small tuft of prickly leaves, often hidden by the grass, but it must be exterminated at once. If let alone, the root-stock extends itself for a long distance in all directions, and branches are thrown up to the surface. These are apparently winter-killed, but the returning summer shows that this is not the case, they are only killed down to the ground, and as soon as favorable weather comes their prickly stems arise from the subterranean buds and stand up in bristly defiance to the cultivator. Wherever a Canada thistle appears, cut it down. We have but little belief in specific applications to weeds, but we have known these and other thistles to be destroyed by cutting as soon as they appeared and applying salt to the portion remaining in the ground. Whether the first year's attempt at exterminating this pest is successful or not, it is a duty that each farmer owes, not only to himself but to his neighbors, to prevent dissemination; let no plant upon the

from my meadow?" etc., we are induced to repeat that weeds are subject to the same laws of growth as other plants, and what will kill the one will kill the other. There are but two ways of getting rid of weeds after they become established: One is to exterminate them, either by such frequent cutting that they will be exhausted, or to dig them out root and branch; and the other is to introduce a cultivated crop that will occupy the ground to their exclusion, and choke them out. The ground has to be occupied with something—if with a well cultivated crop, the weeds stand but a small chance; if by a neglected crop, the weeds and the crop have to fight the battle for possession and the chances are that the weeds will get the best of it. Again we repeat that there is no specific remedy for weeds, any more than there is for human diseases, and any one who advertises either may

premises flower, much less perfect its seeds. Patience and frequent cutting as fast as it appears above the surface, will in time destroy it.

The Legislature of Michigan has recently passed a law requiring every person to cut from his land and the adjoining highways, the Canada Thistles as often as may be necessary to prevent them from going to seed, under a penalty of 10 dollars for neglect. In case the owners of the land should fail to cut the thistles after proper notice, the Overseers and Commissioners of highways of the towns are empowered to destroy them and add the expense of doing so to the tax levy. If a similar law could be carried out in every State, we should hear but little of the Canada Thistle.

Agricultural Colleges.

The Agricultural College Act passed in 1862 donates to each state 30,000 acres of land for each Senator and Representative in Congress. We find the following list of states which have accepted the land grant, in one of our exchanges:

1. Iowa—To select land within her own limits.
2. Rhode Island—To locate with scrip.
3. Minnesota—To select within her own limits.
4. Kansas—To select within her own limits.
5. Illinois—Part selection, part scrip.
6. New-York—Scrip.
7. Kentucky—Scrip.
8. Vermont—Scrip.
9. Wisconsin—To select within her own limits.
10. Pennsylvania—Scrip.

Unless we are much in error, the State of Michigan should be placed with the above. We can not conceive that a State which has, from her own resources, established an Agricultural College and accumulated a fund of experience for the benefit of other states, should be behind her neighbors in accepting the means with which to consummate her costly experiment. The little state of Rhode Island, smallest in territory, but among the first in every patriotic work, was foremost to avail itself of the provisions of this grant, and locate her lands; and now we find Kansas, which was but a short time ago a territory, inviting for proposals from different counties for the location of its Agricultural College. Rhode Island has placed her lands in trust with Brown University to carry out the provisions of the act of Congress, and we have no doubt that this venerable institution will, in due time, give a good account of its stewardship. Most of the states have several colleges, and they can not do as Rhode Island has done for fear of exciting local jealousies. In the majority of cases entirely new institutions will be founded, and as the matter will probably be put in charge of those who have had no experience, we would offer one or two suggestions on the subject.

Do not make the attempt to start an Agricultural College in the wilderness. It is better to begin in a settled and well cultivated region. The students have already seen enough of subduing the forest and of making a farm at their own homes. They wish to see the best culture on cleared land, and will become discouraged if they find nothing better at an Agricultural College than they left at home. Every institution of this kind should have manual labor as one of its absolute requirements. An agricultural college which neglects this branch of education will fall short of public expectation. While we insist upon manual labor as one portion of the instruction in these colleges, we are aware of the difficulty of uniting the theory taught

in the class room with practice in the field. In a somewhat extended experience we have met but few persons who united thorough practical with thorough scientific knowledge of agriculture. The opening of so many colleges where agriculture is taught, both as an art and as a science, will present a new field, and induce our young practical farmers to educate themselves to fill places in them as instructors.

A Few More Humbugs.

One of the meanest attempts at imposition we have met with, is set forth in the following advertisement, published in several newspapers.

DRUNKENNESS CURED.—The inebriate may now bid defiance to the tempting cup. Dr. —'s **ANTIDOTE FOR STRONG DRINK** is a certain cure for drunkenness. It creates a dislike for strong drink, and can be administered without the knowledge of the patient. Price \$1 a box. Sent by mail.

An acquaintance of the writer's who had unfortunately contracted an uncontrollable appetite for spirituous liquors, earnestly desiring to reform, was induced to try a prescription advertised like the above. It made him severely ill, and for a short time kept down the desire for alcohol, but upon his recovery it raged as fiercely as ever, and he drank even more deeply than before. Fortunately he was finally rescued by taking and keeping the total abstinence pledge, which is the only perfect preventive of, or known cure for the habit of drunkenness. The "remedy" proposed, probably consists of tartar emetic, a poisonous substance producing violent nausea, and affecting some persons dangerously. A sufficient amount to "turn the stomach" can be purchased for a few cents of any druggist. At best, its effects will only be temporary, and we repeat, it is a mean swindle to thus trifle with the sorrows and the hopes of the afflicted for the purpose of unjust gain.

ANOTHER "TRANSMUTATER."—A certain "Doctor" sends out from New-York City, a "Journal of Science and Medicine," wherein are contained matters of marvelous import and astounding magnificence. Every disease is to be cured, unbounded wealth obtained, and unlimited happiness realized, all for a few dollars apiece. Here are a few choice samples of this "Doctor's" wares. "Elixir of Life, \$6," "Silver and Gold Fluid, \$5," "Instrument to Discover Treasures, Mines, Minerals, etc., \$3," "Instructions and Means how to make an Enemy fear you, at whatever distance, \$5" (a pledge of Good Motives must accompany the Order). "A Means by which one may go through all Dangers, Troubles, &c., \$5," "String of the Civit Cat, by the use of which one may pass through all Enemies, Battles, &c., without any Danger whatever, \$7. This valuable means is used in our army with the greatest success, and no person who has a friend in the present struggle, should fail to procure one and have it sent at once; hundreds of testimonials can be given, but want of space prevents, and as the 'Civit' speaks for itself (wonderful Civit), it is not required." "Mysterious Electrical and Weird Ring.—Whoever wears it, Never can have an enemy. Just by turning the Weird Seal of this Ring towards the beholders, he will become to them Invisible. In which condition he can do what he or she likes to do, and no one can see How or What is done"—and so on to the end of the chapter. Now "Doctor" Freeman, you know this is all lying nonsense, got up to cheat the ignorant and credulous—but there is no use in wasting words on such a case. Let none of our readers, from curiosity even, hold any communication with such a glaring swindler. Let

him and others like him pay their own printing and postage bills, without aid from our readers.

A WONDERFUL PREPARATION.—We notice in the columns of a respectable agricultural contemporary, an advertisement of a "Sheep Dipping Composition," which is said to "add over one pound of wool to each fleece, besides wonderfully improving the condition of the sheep, at a cost of only about three cents a head." This beats Graham's Unguent for making whiskers grow in six weeks, or the hair preparation recommended to restore the covering on old trunks. Possibly it is made of the same materials. If a sheep be afflicted with scab or other similar ailment that causes the wool to fall off, then a "dip" in tobacco water may save a pound of wool per head; but the attempt to pull the wool over the eyes of farmers by such pretensions as are made in the above advertisement is simply dishonest, and we can not but wonder that it should receive any countenance from a respectable journal.

Japanese Agriculture—Interesting and Instructive Notes.

Dr. H. Maron, has made a report to the Minister of Agriculture at Berlin, on Japanese husbandry, which is full of interesting facts and eminently suggestive. The Japanese cultivator follows a routine which the experience of centuries has marked out, and though there is nothing about their system which indicates progress, their results show that their actual state of cultivation is far in advance of more civilized countries. The area of the Japanese Empire is about the same as that of Great Britain and Ireland, and contains a far larger population; yet Great Britain is obliged not only to import food from other countries, but to also import large quantities of fertilizers to aid in raising its crops. Japan, on the contrary, imports neither grain nor manures, but exports considerable quantities of food. This is the present condition of Japanese Agriculture, taken as a whole. Its details are not such as could be carried out among our people as they bend the whole energies of a large majority of the population to producing the greatest possible amount from a small area of soil. The whole arable land of the country is divided up into plots of from two to five acres each, and their agriculture would be considered by us as a very close system of gardening. The land is kept constantly up to its greatest productiveness, and this is done by a system of manuring and cultivation which may offer some suggestions to our own farmers. In the first place, the Japanese follow deep tillage, the arable soil being several feet in thickness. What is a wheat patch at one month is converted in part into a rice swamp the next. One part of the field being excavated, and the earth thrown upon the other to make an elevated island for the growth of sweet potatoes and other crops, while the lower portion is flooded with water for the rice crop. In this way the whole soil is frequently turned over to the depth of 2 or 2½ feet. Another peculiarity is that the crops, of whatever character, are always grown in drills; sown in this way they can receive the highest possible culture, and special manuring. Each crop is grown with no reference to that which shall succeed it. The system of rotation and fallows is unknown, but the land is looked upon as a bank which will honor any drafts made upon it, if the drawer has only made a sufficient deposit—of manure.

The amount of manure on hand determines the breadth of land which the Japanese farmer will sow. The peculiarity of Japanese husbandry is that no animals are kept. Human excrement forms the principal manure. The Japanese farmer does not allow the crop to be eaten by cattle and then return to the soil the manure from them, but he eats the crop himself, with the help of his family, and returns the manure directly to the soil. The religion of the people prevents their eating any animal food except fish; and they eat the mollusks or "shell-fish" in great quantities, and the manure from them is the only fertilizing material returned to the land that does not come off of it. On the farm, human excrement is returned to the land from which the food came, and the cities regularly return to the country loads of human manure in exchange for the food which they receive. Throughout the country the greatest care is exercised in preserving the night soil. The cabinet or privy, is an essential part of the houses of the poorest as well as of the wealthy. A bucket or earthen vessel is placed where it will receive the deposit and is provided with projecting ears into which a pole can be inserted for the purpose of carrying the vessel. At the towns and cities "thousands of boats may be seen early each morning laden with high heaps of buckets full of the precious stuff, which they carry from the canals in the cities to the country. These boats come and go with the regularity of the post; it must be admitted, however, that it is a species of martyrdom to be the conductor of a mail boat of this kind. In the evening long strings of coolies are met with on the road, who, having in the morning carried the produce of the country to the town, are returning home, each with two buckets of manure, not in a solid or concentrated form, but fresh from the privies. Caravans of pack-horses, which often have brought manufactured articles (silks, oil, lacquered goods, etc.) a distance of 200 to 300 miles from the interior to the capital, are sent home again freighted with baskets or buckets of manure; in such cases, however, care is taken to select solid excrements." For the way in which the manure is treated, we can not do better than to quote the language of this interesting report.

"The excrements are diluted with water, no other addition of any kind being made to them, and stirred until the entire mass is worked into a most intimately intermixed fine pap. In rainy weather, the vessel is covered with a movable roof to shield it from the rain; in dry weather this is removed, to allow the action of the sun and wind. The solid ingredients of the pap gradually subside, and fermentation sets in; the water evaporates. By this time the vessel in the privy is again ready for emptying. A fresh quantity of water is added, the whole mass is again stirred and most intimately mixed together, in short, treated exactly like the first emptying. The same process is repeated, until the cask or pan is full. After the last supply of excrements, and thorough mixing, the mass is left, according to the state of the weather, for two or three weeks longer, or until it is required for use; but under no circumstance is the manure ever employed in the fresh state. This entire course of proceeding clearly shows that the Japanese are no partisans of the nitrogen theory, and that they only care for the solid parts of the dung. They leave the ammonia exposed to decomposition by the action of the sun, and its volatilization by the wind, but take the greatest care to shield the solid ingredients from being wasted or swept

away by rain, &c. As the peasant, however, pays his rent to his landlord, not in cash, but in a certain stipulated percentage of the produce of his fields, he argues quite logically that the supply of manure from his privy must necessarily be insufficient to prevent the gradual exhaustion of the soil of his farm, notwithstanding the marvellous richness of the latter, and in spite of the additional supply of manuring matter derived from the water of the brook or canal from which he takes his material for irrigation. He places, therefore, wherever his field is bordered by public roads, footpaths, &c., casks or pots buried in the ground nearly to the rim, urgently requesting the traveling public to make use of the same. To show how universally the economical value of manure is felt and appreciated in all classes of society in Japan, from the highest to the lowest, I need simply state the fact that, in all my wanderings through the country, even in the most remote valleys, and in the homesteads and cottages of the very poorest of the peasantry, I never could discover, even in the most secret and secluded corners, the least trace of human excrements. How very different with us, in Germany, (and in America.—Ed.) where it may be seen lying about in every direction, even close to the privies! I need not mention that the manure thus left by benevolent travelers is treated exactly in the same way as the family manure.

The Japanese farmer prepares also *compost*. As he keeps no cattle to turn his straw, etc., into manure, he is forced to incorporate this part of his produce with the soil without 'animalization.' The method pursued to effect this object consists simply in the concentration of the materials. Chaff, chopped straw, horse-dung, excrement gathered in the highways, tops and leaves of turnips, peelings of yams and sweet potatoes, and all the offal of the farm, are carefully mixed with a little mold, shoveled up in small pyramidal heaps, moistened and covered with a straw thatch. I often saw also in this compost, heaps of shells of mussels and snails, with which most of the rivulets and brooks abound, and which, in all parts close to the seashore, may be obtained in any quantities. The compost heaps are occasionally moistened and turned with the shovel, and thus the process of decomposition proceeds rapidly, under the powerful action of the sun. I have also often seen the shorter process of reduction by fire resorted to when there was plenty of straw, or where the manure was required for use before it could be got ready for use by the slower fermentation process."

It will be seen, from the foregoing that the Japanese farmer applies his manure only as a top-dressing and in the liquid form. The manure being fully fermented, is brought into immediate contact with the seed, not only without injury, but with decided benefit to its early growth. Another feature which characterizes their culture is the manuring with every crop. Each sowing receives the necessary amount of manure, and a full return is expected from the immediate crop without reference to the next harvest. We have introduced this subject to show that for thousands of years, a successful system of agriculture has been carried on mainly by the aid of human excrement, in the hope of inducing our readers to add this element of fertility to their farms. There exists a sort of prejudice against the use of night soil as a manure. A general knowledge of chemistry would dissipate this and other notions. Human excrement, as well as that of animals, contains

elements which are needed for the growth of the plant. It matters nothing from what source these are obtained, the wondrous processes going on within the plant will convert these elements into food. Every thoughtful person will see that it is man's duty, when he has taken the products of the soil for food, to return to it those portions which are not needed in his own system, but which are, according to the operations of nature, voided in such a state as to demand their removal, and which form valuable plant food.

Statistics of the Tobacco Crop.

The following figures published in the Massachusetts Agricultural Report for 1862, show the immense commercial importance of this crop.

The product in the United (and seceding) States and Territories, in 1849, was 199,752,655 pounds. In the year 1859 it reached the astonishing amount of 420,390,771 pounds, being a gain of 220,638,116 pounds in ten years. The crop grown in 1859, at the low figure of ten cents per pound, would amount to \$42,039,077. Notwithstanding the great amount grown here, we find that large quantities are imported every year. Not being able to get the amount imported in 1859, we take that of 1858. In that year there was imported into this country, 7,499,566 pounds, at a cost of \$1,255,831. Also 218,729,000 cigars, at a cost of \$4,123,208, and snuff, with other manufactures of tobacco, to the amount of \$589,439. Of the domestic tobacco spoken of, there were exported 127,670 hogsheads, 4,841 cases and 12,640 bales, valued at \$17,009,767, and of the manufactured domestic tobacco exported, there were 11,210,574 pounds, valued at \$2,410,224.

By the census of 1840, all the tobacco grown in Massachusetts in 1839, amounted to only 64,955 pounds. In 1849 the amount was 138,246 pounds, all grown in four counties, viz.: Franklin, 14,590 pounds; Hampden, 68,156 pounds; Hampshire, 55,300 pounds; Middlesex, 200 pounds. In 1859, Massachusetts produced 3,223,198 pounds, being an increase of 3,084,952, the last ten years, and in twenty years 3,158,243 pounds. It is estimated that Massachusetts has produced this year (1862,) one-third more than 1859, which would make the amount 4,297,597 pounds. At fifteen cents per pound, (which is a low estimate for this year,) this crop would come to \$644,639.55. Several of the northern States present a very large increase. Ohio raised in 1859, over twenty-five and one-half million pounds. New-York increased her product the last ten years, from 83,189 pounds to 5,764,582 pounds. Connecticut increased from 1,267,624 to 6,000,133 pounds. In 1849 the loyal States produced 230,369,341 pounds, and the seceding States produced 199,021,430 pounds. The consumption of this article, in various forms, doubtless keeps pace with the production.

Sweet Potato Vines for Cattle.

"Experience" writes from Monmouth Co., N. J., as follows: "I have used sweet potato vines for cattle, for the past five seasons with admirable success. If care is taken to rid the vines of the dirt which generally adheres to them when pulled, cattle will eat them as readily as they will the best of pasture. In fact I have seen cattle, when vines were thrown into their field, leave first rate pasture and come bellowing for a feast. I do not hesitate to say that sweet potato vines can be used to great advantage for both hogs and cattle."

The Wonderful New Strawberry—The Plants to be Presented to the Public.

None but those who were at the *Agriculturist* Office on Thursday, June 18th, can have a full conception of the enormous size to which this delicious fruit has been grown. The accompanying engravings (fig. 2, 3) are exact sketches of two of the berries of the New Seedling, taken from accurate measurement with calipers. These were not abnormal specimens, of chance growth, for there were plenty more nearly as large. And what is remarkable, the berries were not hollow, nor poor flavored, but were solid, a rich crimson color to the core, and of excellent flavor, having the pleasant pine taste of one of the parent plants. The general form is that of fig. 2, conical and partially necked. The plant itself bears large leaves, is very vigorous, and shows a good bearing propensity. Taken all in all, this new seedling is probably the largest and the most remarkable production in the Strawberry way, that has ever appeared.

Its Origin.—Mr. Seth Boyden, upon the results of whose inventions in the manufacture of polished leather (called "patent leather,") and in the production of malleable cast iron, etc., much of the growth and prosperity of the large City of Newark, N. J., depends, has for many years devoted more or less attention to the improvement of the Strawberry. "Boyden's Mammoth," and "Boyden's Green Prolific," are widely known. The Green Prolific he has hitherto considered his best product. It was obtained by hybridizing Hovey's Seedling, and Kitley's Goliath. Following up his experiments, he hybridized the Green Prolific with Peabody's Seedling, the latter a large, excellent pine berry, but too little productive to meet with general favor. One of the products of this last hy-

bridization, is this new seedling which has recently attracted so much attention.

The Name.—Mr. Boyden simply called it his "No. 10" Seedling. It was proposed by some to call it the Seth Boyden; by others, Boyden's Giant; by others, Boyden's Wonderful, and so on. But to avoid confounding it with the already well known Boyden's Mammoth, it has by common consent been named the "*Agriculturist* Strawberry"—partly because brought out at the *Agriculturist* Exhibition, and partly because, at large expense, the Proprietor of this journal secured all the plants, and is cultivating them for free distribution.

The Purchase of the Plants.—No one outside of Mr. Boyden seems to have known anything of this new variety, until he came in quietly at the opening of the Exhibition, and placed upon the table the plates of berries, and a growing specimen of the plant. It at once attracted much attention, exciting the admiration of all who saw it, and there was an eager desire to get the plants. Mr. Boyden, who is noted for looking out very little for his own interest, while contributing so much to the prosperity of others, accepted the first offers, voluntarily made to him, of one to three dollars each. Some of the enterprising clerks in the *American Agriculturist* office immediately called the attention of the Proprietor to the matter, and proposed that it be secured for distribution. He at once examined the fruit and plant, and seeing its great merits, made Mr. Boyden an offer for all the plants unsold, which offer was promptly accepted. In order to keep the plants pure, and prevent speculation in them, he bought up at \$10 each those plants already sold, except a single one in the hands of an amateur friend, who will cultivate it only for his own personal use. M. Olm immediately went with men and teams to New-Jersey, and took up all the

original plants carefully, and transplanted them to the Proprietor's grounds at Flushing, where they are now doing well, not one having been lost, though moved 25 miles in the hot days of June 22d and 23d. M. Olm, than whom there is no more skillful cultivator in the country, has them in special charge, and will multiply them as rapidly as possible. There is little doubt that several tens of thousands of plants will be ready for distribution during next season (1864). The design is to make this, the greatest and best production of this delicious fruit, a free gift to the public. No plants are offered for sale on any terms, though as high as \$50, and even \$100 dollars, have been offered by enterprising cultivators, for a single plant.

Plan of Distribution.—The plants will be distributed during the year 1864, and as our experience has proved that they can be sent safely by mail, hundreds and even thousands of miles, this mode will be adopted for all who do not live near enough to take them by hand. Those living at a distance will therefore be on a par with those residing here. We purpose to produce as many plants as possible, and send them out to all subscribers to the *American Agriculturist*, and that will embrace pretty nearly everybody in the country who takes an interest in such matters. The number of plants will depend upon the weather from this time onward. We hope to have 100,000 plants, which will give at least one to every subscriber. Let there should be any failure in getting enough for all, we shall begin at once to enter down the names of all subscribers for 1864 who desire the plants, beginning with the 1st of July, and supply them in the order of receiving the names. (As soon as our intention was known, many persons who saw the plant and fruit at once subscribed ahead for 1864.) We feel safe in promising 30,000 to 50,000 plants at least. Those whose subscriptions already extend to next year, need only to send in their application, with the trifling sum named below, and their names will be put down for the plants.

Expenses of Distribution.—The expenses of purchasing, propagation, etc., will amount to some

Fig. 2.

thousands of dollars, which we will cheerfully pay. In the distribution, the cost of postage and oil cloth will be about 5 cents for each parcel. This small sum, small to each, but large in the aggregate for 50,000 to 100,000 parcels, should be met by those who receive the plants. We therefore ask each one who desires the plants to enclose an extra 5 cents along with

the application. As there must be some limit, we know of no better one than to make the distribution to subscribers for volume XXIII, (1864). We therefore repeat.

The plants are offered free to ALL persons receiving the *Agriculturist* for 1864, (exchanges included), who apply for them, if there be plants enough for all, and if not, the plants will be sent as far as they go to those first applying, in the order of the receiving of the names for 1864—the only charge being the cost of postage and oil cloth (5 cents) as above.

A single plant can be rapidly multiplied to hundreds. We once made about 1200 plants in a single year from 6 plants that had been ten

food; and never enjoyed better health. Those delicious berries did not cost a cent a quart, aside from the picking, and the labor of picking was trifling, for not "a great many made a quart." Every member of the household was also similarly supplied, and several friends shared with us. Besides, we bottled three pecks for next Winter, and the grocer came and bought enough to pay the entire expenses of the whole! The saving in meat and other food, to say nothing of health, would have paid the expenses three times over, if the grocer had not. All this came from less than four rods of ground, which was only set to vines last year, partly in September, but mainly in April. Does any reader wonder that after such experience we are earnest in our effort to induce all the members of the *Agriculturist* family to grow strawberries if we desire to promote their pleasure? Other fruits are good in their season, and should be under culture, but years of time are required to get the tree fruits. Strawberries set in Spring yield abundantly the next year, and those set early in Autumn yield a partial supply the next Spring, and are in the height of bearing the year after. The next month of September, and the first of October is perhaps the best time to begin, the earlier the better. The last of August is a good time when the plants are not moved far enough to require packing. The plants of good standard varieties are now within the reach of almost every one. Under the new postal law, plants go every-

where to the most distant States and Territories, for 2 cents postage on each 4 ounces. A few cents' worth of oil cloth will envelope them securely. We have demonstrated that they can be sent hundreds and even thousands of miles by mail, and safely, especially in the cool weather of Spring and Autumn. Of 40,000 plants distributed by us to subscribers last year, nearly the whole lived, and have already multiplied to millions. Our advertising columns, this month and the next, will doubtless tell where an abundance of plants can be obtained by mail. As noted elsewhere, next year we shall offer, free to all our subscribers, plants of the largest strawberry yet produced. But do not wait for that. Try your hand this year at raising some of the good sorts already before the public in abundance. There are the *Triomphe de Gand*, the *Bartlett*, the *Austin*, the *Wilson*, etc., any one of which is better than wild diminutive sorts, or even the older improved kinds. A small sum will buy a dozen to a hundred plants.

Any Soil Will Do.—There are only two exceptions to this rule, viz., soils too sandy and barren to bear anything, and those subject to standing water. The freezing of standing water in Winter is apt to kill all the plants. Good corn ground is good for strawberries, though they need more water than corn to produce the best results. We have seen first rate crops of strawberries on very heavy clay land, which had been deeply plowed and lightened up by a large mixture of leached ashes, with an open drain or two to carry off surplus water. Any soil is improved for strawberries by working into it a good quantity of rotten manure and black mold from the woods.

Strawberries Will Grow Everywhere.—We should hardly attempt to grow them at the North Pole, but they can be grown about as far north as civilized society extends at present, and as far south as the equator. North of 40° or 41°,

a slight covering of straw is useful in Winter, and necessary for most varieties north of 42° or 44°. The main requirement is to prevent the destruction of the plants by freezing and thawing. In the moist climate of Great Britain the same varieties grow larger than with us, but inferior in flavor. They require but a short season of warm weather to perfect their fruit.

Varieties.—The *Wilson's Albany* is a popular variety, because it yields large crops of large and beautiful berries. For our eating it is too acid, when sugar is so costly as now. For general culture we prefer the *Triomphe de Gand*, which bears nearly as well, the fruit of better flavor, and equally as good in appearance, and the plants are less apt to die out after heavy bearing. The *Austin* is a great bearer and the fruit large, but it is not so firm, and not quite equal in flavor. Its prolificness, its hardiness, and long bearing render it worthy of a place in a family assortment. Two or three kinds are preferable to one, both for variety and to lengthen the season. The *La Constante* is one of the most beautiful strawberries in appearance, is excellent flavored, and desirable in a collection, but plants are not very abundant or cheap this year. There are many other desirable new sorts, but we are only speaking now of a few of the good varieties so abundant as to be accessible to the millions. The *Triomphe de Gand*, the *Wilson*, and the *Austin* will supply an assortment that will give satisfaction to the great mass of people.

HINTS ON CULTURE.—Strawberries will grow without any culture; they will thrive under moderate care; they will repay the best attention. If one has but few plants and the first object is to multiply them, prepare a well manured plot, digging in thoroughly a free supply of decomposed or half decomposed manure, and set the plants two to three feet apart each way, so as to leave room for runners. The strawberry is multiplied by runners which start out in every direction, and take root at the joints of the runners. When well rooted, the runners may be cut between each two new plants. A level surface of fine soil is best for the runners. If anxious to get as many plants as possible, put a little crotched limb, or a lump of earth, or a small stone, over the runner near each joint, so as to insure its taking root there. Usually this is not necessary, unless there be considerable wind to sway the runner and disturb the catching of the roots. If two or more runners start together, they may be moved apart, or the direction of one be changed so as to distribute the new plants well over the ground. The first plants formed on runners starting in July, will usually produce other runners during Autumn. If carefully transplanted in August or early in September, each young plant may become the parent of many other plants before frost. By this process, we have made half a dozen plants set in Spring, cover 500 square feet thickly with new plants during the same season.—The fruiting plot will become thickly studded with plants in Autumn, unless the runners be clipped or removed as fast as formed. In regard to manuring, the whole soil may be made fertile. We are however, pursuing the following plan with our New Plants. They were set 3 feet apart in soil moderately manured and prepared for other crops. Then a coat or mulch of half rotted manure was spread upon the surface around each plant, and the water applied, washed some of its strength down into the soil, while that remaining upon the surface, acts as a mulch to keep the ground moist. This is one of the

Fig. 3.

days in reaching us. They had met with such hard usage that only six lived out of a dozen received, and those were very weak. It will be seen then, that our mode of distribution will soon scatter them over the whole country, as we have subscribers at more than three-fourths of all the Post Offices in the Loyal States, and in the British Provinces.

The plants are not offered as prizes, but rather as a gift to all subscribers who receive the *Agriculturist* for 1864. If any present subscribers prefer to be among the first on the list, they can do so by sending in their subscriptions now for the next year, to begin when their present subscriptions close. New subscribers, beginning at the middle of the present volume, will go on the same list.

N. B.—All persons sending in subscriptions will confer a special favor by stating whether their names are already on our books. It will save us much extra labor in arranging the names upon the mail books.

Good Strawberries—At Least Two Bushels for Every Family.

Yes, two bushels of good delicious fruit, the berries larger than walnuts. A single rod of ground, a few hours' work, and 25 to 50 cents for plants to start with, will do it. We wish we could impress this fact so strongly upon every family in the land that they would set about the work at once. Everybody loves strawberries; they are grateful to the taste, and healthful. They will grow wherever corn will grow, and in many places where corn will not ripen. They are almost as easily cultivated as corn, and will even flourish on poorer soil.

See here! From June 12th to July 4th our own personal rations included a quart of fine strawberries every day, part in the morning and the rest at evening. We eat much less of other

best methods of applying manure to any plants or shrubs which have been transplanted.

For General Culture or Fruiting.—There is need for but few directions. Choose any soil, the best that can be spared: spade it deeply, and if not in good heart, mix all through it a fair supply of rotten manure, muck or sods, or better still, black mold (black earth from the forest). This is not necessary, but is desirable, in order to get the best results. Leached ashes mixed in plentifully, are also good, especially for heavy clay soils. Too much fresh manure will produce an over growth of plants at the expense of fruit, though a fair supply of any kind of manure is not objectionable for plants set in Autumn. We prefer dividing the ground into beds $4\frac{1}{2}$ feet wide, with three rows of plants in each, one in the middle, and the others 7 inches from the sides—setting the plants 15 to 18 inches apart in the rows. The plants can then be worked and picked from the alleys between the beds, without treading on the beds at all. If there are plants enough, the runners should be picked off as they appear, keeping the original plants in hills. If more plants are desired, let them grow between the hills, and then remove them. The best fruit is obtained by keeping the plants separate in hills.

Strawberry Experience.

The following communication from William F. Heins, Esq., of Morrisania, N. Y., embodies his experience with the different varieties for the present year. The opinion of Mr. H. has great value from the fact that he is purely an amateur cultivator, and has no interest in the sale of either plants or berries, but gives his observations upon the endurance and prolific quality of the plants, during the past unfavorable season, entirely from their behavior in his own grounds. "In most locations the crop may be considered nearly a failure, and I think the principal causes were: 1st, the changeable Winter; 2nd, the hot and dry weather following, and 3d, the sudden and heavy rains while the plants were flowering. My soil, gently slopes to the S. E., is an excellent, medium heavy loam, thoroughly worked to the depth of 30 inches, and rich in completely decomposed vegetable matter. The result of my observations upon the 65 kinds I cultivated is the following: The Triomphe de Gaud I put at the head of the list, and with me, old and new beds, attended to or neglected, gave plenty of fruit, and showed least signs of suffering; the plants remained vigorous, and are bearing now, July 6th, a quantity of sound and excellent berries. The next, mentioned in the order of their excellence, were Lennig's White, White Pine Apple, White Albion, Wilson's Albany, and W. A. Burgess' new seedlings, General Scott, Garibaldi, Gen. Lyon, Monitor; Hot-house Pine. The three first ones gave plenty of fruit, were of vigorous and healthy habit; then I name Burr's New Pine, Russell's and Downer's Prolific, Early Scarlet, Ladies' Pine, Empress Eugenie, Scott's Seedling, Scotch Runner, Jeany Lind, Bartlett, Hooker's Seedling, McEvoy's Superior, Cutter's Seedling, Honneur de la Belgique, Bonté de St. Julien, La Constante, (the last two of very excellent flavor), Nero, Black Prince, Red and White Alpine, Duc de Malakoff. As all the other sorts suffered more or less and yielded only a very moderate crop, it is not necessary to enumerate them. It is probable that in more favorable seasons some of these will prove more valuable than they seem to be at present.

Currants and Gooseberries.

The season of strawberries passed away with June and was succeeded by the less delicious but still acceptable currant. The currant is one of our most reliable fruits, and we refer to it at this time, because we desire every reader of the *American Agriculturist* to be thoroughly impressed with the importance of the small fruits, both as a matter of health and economy. We hope every one of them will have a constant and full supply of strawberries, currants, gooseberries, raspberries, blackberries, etc., as long as the season lasts. A currant patch is easily started; if neglected it will bear tolerably for years, and with a little care in pruning it will continue to yield abundant crops of fine fruit which is excellent fresh, dried, made into jelly, or preserved in bottles. The time that fruits are in perfection is the one in which to talk about growing them. All our plans, whether for the farm or garden should be laid well in advance. Let every farmer who is without small fruits determine to have at least a patch of currants, and strawberries; grapes, and other fruits will soon follow. Currants are raised with the utmost ease. Good rooted plants from the nursery set this Fall will give a some fruit next season. Those who cannot afford to send to nurseries or are not in reach of them, can always get cuttings of some neighbor. Cuttings of this year's wood, about a foot long, are to be taken as soon as the leaves have fallen: cut out with a sharp knife all the buds except three or four of the upper ones, and then plant in rows 6 to 12 inches apart, burying them for two-thirds of their length. If set into good soil, not ten in a hundred will fail to make plants, which next year may be set out where they are to stand. In after culture the currant is grown in several different ways. It may be grown upon a single stalk in the form of a tree; it may be trained upon a wall, fence or trellis; or it may be grown upon a sort of renewal plan. According to the last method, the eyes or buds which go below ground are not taken out, but the plant is allowed to shoot up from the root, and the branches which come up are cut out after they have borne one crop of fruit. If the plants become crowded, a portion of the new wood should be cut out. This manner of growing currants is, by many cultivators, preferred to the tree form. A hoop is sometimes put over the bush, to which the branches are trained, thus giving all an equal chance at the light and air. We have seen such fine crops grown with both methods of cultivation, that we hardly know which to recommend. When the bushes are trained upon a fence or trellis, they should be encouraged to make only two stout branches the first year. These are to be laid horizontally, and the limbs which they throw out are to be trained in an upright position. Currants may be made to give a large crop and take up little room, by training them against a fence; they may be planted within six inches of it. With regard to varieties there is considerable choice. We say, grow currants at any rate, and take the common red, if nothing better is within reach. Where they can be had, the Cherry currant and the White Grape are to be preferred. Even the common sorts will yield larger fruit by good culture and close pruning. The gooseberry is very much neglected of late for the reason that the varieties most celebrated in Europe are rendered worthless in our country by mildew. Of late two American sorts, Houghton's seedling and the

American seedling have been introduced, which are quite free from this defect. They are pretty sure to give a crop, though the berries are small. We recently saw on the grounds of J. C. Thompson Esq., at Staten Island, a fine large seedling berry which was very productive and very free from mildew. Mr. T. expects to get 20 bushels from a small patch, and judging from the appearance of his bushes we should think that this amount might be gathered. Should this berry produce as well and prove as free from mildew in other localities, as it does in the grounds of Mr. Thompson, it will be a decided acquisition. The gooseberry, when green, possesses a sprightly acid flavor which will always render it popular for either pies or "sauce."

Another Enemy to the Fruit Grower.

Prof. G. M. Smith, of Tippecanoe Co., Ind., has sent us specimens of an insect which seems to be of the most destructive character. It strips the leaves from the trees by cutting off the leaf stalk, and eats the bark from the young shoots, and in some cases attacks that of the last year's wood. It does its work of devastation so thoroughly that not a leaf or young shoot was left on about 50 trees which were attacked. Not recognizing the insect, we forwarded specimens to Prof. Glover, of the Agricultural Department at Washington, who has kindly furnished us with the name and the drawing from which the engraving is made. It is the *Rhyacionia curculionoides*, belonging to the same order with the well-known curculio, and is one of its largest representatives. It has been called the New-York weevil. The insect is of a gray color, having upon each wing-cover four white lines interrupted by black dots. Its attacks are not confined to fruit trees, as it is also found on the oak and maple. Fortunately this pest does not seem to be very abundant, and wherever it appears, it should be captured, by jarring the trees under which a sheet has been placed, in the same way that has been described for the destruction of the curculio, on page 164.

Renewing Old Grape Vines.

Many persons have large, ill-shaped vines, clampering over arbors and trellises, which they would like to bring into better shape and more fruitfulness; but they don't know exactly how to do it. There are several ways: First, lay down a good, vigorous cane on each side of the main trunk, burying it for two feet or more in length, with six inches of dirt. In one season, or at most two, these canes will be finely rooted, when the old stump may be grubbed up. The new layered plants may afterward be trained according to any of the received methods. Another way would be to retain the old root, but to change the top by degrees. Cut out in the Fall, one fourth of the large canes on one half of the vine; train up the handsomest new shoot that pushes during the Summer; and in the Fall, cut away all others on that side of the vine. This shoot retained is to form a horizontal "arm" for training up perpendicular canes from. Next year, proceed in the same way with the other side of the vine. This work of renewing the vine ought to be done gradually, and extend over a period of three or four years; since, if the old canes are cut away at once, the

new growth will be long-jointed and succulent, and poorly fitted for good horizontal arms.

Experience with Grape Cuttings.

Mr. D. N. Allard, sends to the *Agriculturist* the result of his experiments with fifteen thousand grape cuttings, taken from the vines at various times from December to March 1st. He planted all the cuttings in the same manner and found that of those made in February, twice as many grew as of those taken in December. This he accounts for by the fact that the partially ripened wood had been killed off by February, and was rejected in making the cuttings at that time, while in December the wood was all alive, but the fully and the partially matured were both used. Most of his beds of cuttings were shaded by branches supported upon frames five or six feet above them—while three beds were left unshaded. The result was that more than twice as many cuttings rooted in the shaded beds as in those without this protection.

Azaleas, Rhododendrons, and Kalmias.

It surprises English visitors to this country, that we make so little of these native flowering shrubs. In the old world, especially in the British Isles, they are a favorite feature in ornamental grounds. They are set in picturesque groups and masses, in soils carefully prepared and suited to their wants, and are styled, by way of distinctive honor, "the American Garden." Mr. Hovey tells us that "every Spring these shrubs are transplanted in the Regent's Park and Royal Horticultural Society's Garden, where they are arranged in neat beds, and protected with an awning, retaining their beauty for weeks, and attracting immense crowds of admiring visitors. After their bloom is over, they are removed to the nursery-grounds from whence they were taken, receiving no injury, so easy are they to transplant at all seasons."

Why should we leave it to foreigners to find out before us, the merits of our own plants and trees? Like our books, they have to go abroad to get a reputation before we appreciate them. But the few who do know them, are becoming zealous in their attachment and most enthusiastic in their praise. One reason why they are so seldom planted, is the prevalent impression that they are hard to transplant; whereas, if properly treated, nothing is more easy. If taken from the shade of a dark swamp, and set in the glare of a sunny garden, it is not strange that they wither and die.

The *Rhododendron maximum* of our Northern swamps does not seem to do so well in cultivation as its more Southern brother, the *Rhododendron Catawbiense*; this has been hybridized with some of the brilliant Indian sorts, and a great number of varieties of exceeding beauty have been produced. The Azaleas now procurable are a great improvement on our native species. We have the pink, yellow, orange, and flame-colored, which make the garden all ablaze with bloom. The *Kalmia* is beyond improvement. It is less fastidious than the rhododendron or azalea about soils, and will do well in any garden not too dry. All these plants in a wild state seem to prefer the steep banks of streams, or the sides of hills sloping northward. This northward slope protects them from the burning suns of mid-day, and gives them the partial shade and cool atmosphere they delight in. To any of our readers preparing to set out these shrubs, we would recommend the trial

of such a situation and such soil; if not at command, let the treatment be as follows: Choose a spot rather sheltered from harsh winds, surround it with a belt of evergreens, or at least with a screen on the south side, throw out the natural soil of the bed for eighteen inches or two feet deep, and fill up the space with a compost of good garden loam, sand, and fibrous peaty earth. Give the plants a thorough watering when set out, then cover the ground with three or four inches of forest leaves. One writer warmly recommends a mulch of sawdust. The girdle or screen of evergreens is needful both to keep off the bright rays of the sun in Winter and Summer, and to protect the plants from too sudden changes of temperature. Once a year, it will be found advisable to cut off with a spade the roots of the surrounding evergreens, because they will naturally push into the rich feeding ground of our plants and rob them. It is possible that the partial failure of some planters is owing to the practice of setting the roots of their plants too deep. In their native conditions, they do not send their fibrous roots deep into the ground, but spread them out in a sort of net-work near the surface, ramifying among the half-decayed leaves and rubbish of the top soil. Follow nature's hint, and do not forget the indispensable mulching. The deep trenching we have recommended is needful to furnish a reservoir of moisture for the roots in dry weather, but not to bury the roots in, and the mulching is useful to keep that moisture from evaporating. It is one excellence of the rhododendron, that it can be safely transplanted any time from April to October. We have often reset them when just opening their blossom buds, and have had good flowers the same year in which they were transplanted.

Substitute for a Green-House.

Lovers of plants will manage to grow them in spite of all difficulties. We have published several ingenious plans contrived by those who can not command a green-house, for the preservation of their favorites. Mr. S. A. Myers, of Henry Co., Ohio, writes us, that "having but two acres of land and at present a cabin house, the pretty green-house would make rather a striking contrast, and yet I am not willing to do without flowers even of tender varieties. Our house being too cold to protect them, I have made a close fitting glazed box, 4 feet long, 3 feet high, and 2 feet 4 inches wide, which is placed on wheels and kept in the house; it is accommodated with several shelves in order to bring the small plants near the top. The result is, that I have succeeded in keeping in a healthy state, 4 varieties of roses, 5 Geraniums, 4 Fuchsias, 2 Pinks, 3 Cactuses, 1 Pelargonium, 1 Lemon scented Verbena, Ageratum, Petunias, Verbenas, 1 Jerusalem Cherry, etc.

Floral Zodiacs.

A lady correspondent is mystified about this learned expression. An explanation is easy. As used in garden-books, it means an arrangement of pleasure-grounds, by which the flowering shrubs and plants of each month are arranged by themselves. Suppose we have a garden walk 150 feet long, running in a circle if convenient. We will divide this off into eight or nine sections, called by the names of the months, which we will mark by stout stakes. On finding out the month in which every known

plant blooms, we will place the plant in the section where it belongs; and so, when our collection is full, we shall have a floral zodiac. The April and November sections will require less space than the others. August, September and October will demand the largest room. A walk through such a zodiac would be both charming and instructive. Such a zodiac was first devised and executed by Daubenton, an eminent French gardener and botanist. The scene of his labors was the garden of Luxembourg. He styled it "the grove of the months."

The Perennial Phloxes.

We have often advocated the growing of perennial flowering plants. They are less troublesome than the annuals and bedding plants, and a few of them should find a place in the smallest gardens. The Phloxes make a great show, remain a long time in bloom, and present a great variety in color. The newer sorts have every shade from pure white to dark purple. Some, like Harlequin and Van Houttei are pleasingly variegated. *Alba perfecta* is a fine white. *Roi des Roses* a good rose color. *Minerva* is of a rosy lilac with crimson centre, and *Atropurpurea* is of a deep purplish rose. The catalogues have a host of varieties; we mention the above because we have cultivated them. A mass of different sorts with strong contrasts of colors is a fine sight.

Double Flowering Trees and Bushes.

Of these, there are many. The double flowering cherry is a pretty thing, and blooms abundantly. The double Peach has several fine varieties, such as the rose-colored, the newer crimson, and the white. Lately, we have heard of a carnation or striped, and a camellia-flowered. For free, luxuriant bloomers, commend us to the flowering Hawthorns, crimson and pink. And if the common single apple blossom is beautiful, much more so is the double. Among shrubs, the old flowering Almond, pink or rose-colored, should never be overlooked. More recent additions to this family include the double white and large single-flowered Almond, pure white. Reeve's double *Spiraea* is a gem in its way. The *Prunus triloba* is spoken of as very fine, but we have not yet seen it.

Pillar Fuchsias.

The true beauty of the flower of the Fuchsia is not seen when it is looked down upon. The finest display we ever saw was where the plant was trained to the rafters of a rather low green-house. The flowers, hanging where it was necessary to look up at them, made a most magnificent show. Something of this effect can be obtained by training the Fuchsia, cutting back the branches to the height of 6 or 8 feet. Two or three of different colors trained in this way and planted out against a pillar for support, produce a grand effect. They should be put in a rather sheltered and shaded situation.

ECONOMY IN CUCUMBERS.—In England, cucumbers can only be successfully grown under glass, and some of the varieties grown there have very long fruit. A recent foreign treatise on the cucumber and melon tells us, that it is the custom with some, to cut off a portion of a cucumber, and leave the remainder to grow on.

Grape Trellises Again.

In the *Agriculturist* for April we gave Mr. Knox's plan for a grape trellis, and it has been adopted by a number of our readers. We now present the form used by Mr. A. S. Fuller, the well known horticulturist of Brooklyn. The article is an extract from a forth-coming work, by Mr. Fuller, on the culture of the grape. A plain and practical work upon the grape is much needed, and we shall be disappointed if the work alluded to is not just what is at present required by the inexperienced grape grower.

"The usual manner of making grape trellises with wires running horizontally, is not only very objectionable, especially when the vines are trained with horizontal arms, but it is a much more expensive method than the one shown in the engraving below, consisting of two horizontal bars, and perpendicular wires. Every-body

Fig. 1.—FULLER'S GRAPE TRELLIS.

who has made trellises in the ordinary manner, is aware of the difficulty of keeping the wires straight, even if the posts to which they are fastened are not more than eight feet apart, as the wire will contract and expand at every change of temperature, being loose on hot days and tight on cold ones. Besides, much larger wires must be used, if put on horizontally, to support the fruit and the vine. But the most serious objection that I have found is, that the wires, unless very near together, are not where they are most needed when the young bearing shoots first start, for they must be tied to something to support them when only a few inches long, or they are very liable to be broken off by heavy driving rains. If the wires are eight inches apart (which is nearer than the usual custom to place them) the young shoot must be at least twelve to fifteen inches long before the strength of the vine will admit of its being tied to the horizontal wire; besides, when tied, the strings will allow the shoot to slip lengthwise of the wire, and often it will crowd or become entangled with its neighbors. To tie the vine very tight to the wire, would cause it to become girdled as it expanded in growth.

The above are but a few of the difficulties which I have had to overcome in using the

Fig. 2.—FULLER'S TRELLIS WITH THE TRAINED VINE.

common grape trellis with horizontal wires or bars, and to avoid these difficulties I have adopted upon my own grounds (for low trained vines with single arms) a trellis constructed like the one shown in the above illustration. (Fig. 1.)

It is built in the following manner: Select posts of good hard durable wood of from 4 to 6 inches in diameter and 6½ feet long, set them in the ground 2½ feet deep and in a line with the vines and 8 feet apart, that is if the vines are that distance apart: a post should be placed between each two vines at equal distance from each. When the posts are set, nail on strips 2½ inches wide and ¾ to 1 inch thick, one strip or bar being placed 1 foot from the ground, and the other at the top of the posts; then take No. 16 galvanized iron wire and put it on perpendicularly, twisting it around the lower and upper bar, each wire being placed just where the upright bearing shoots are to grow. It is well to lay down the arms by the side of the lower bar and make a mark on it where each wire is to be put, before fastening the arm; then remove the arms to one side while putting on the wire. If a wire should not be in the exact place where it is wanted it can be easily moved to the right or left, provided it is only twisted around the bars. The distance between these upright wires will differ according to the variety of vine, as the distance between the buds varies very materially in different varieties, but usually 8 inches will be the proper distance, sometimes wiring at every bud and with others only at every alternate one. It will readily be seen that in this mode of making a trellis, when the young shoots start, they can be tied at any time

when necessary, and there is no need nor is it judicious to tie them tight to the wire; they should be left at least one inch from it, the two shoots being tied to the one wire. The cost of wire is about one-fourth of that when large horizontal wires are used. The arms should be fastened to the lower bar either by strips of leather tacked on, or by tarred twine tied around the arm and lower bar."

[Fig. 2. represents the trellis with the vine trained according to Mr. Fuller's system. We should remark that the two engravings were sent to us as one, and in cutting to fit our columns, the left hand post in Fig. 1, and the right hand one in Fig. 2, are represented only half the proper thickness.—ED.]

Making Cuttings.

A large number of our plants are propagated from cuttings, and as this is the season at which many are started for winter blooming, a few hints upon the rationale of the process will be timely. A plant may be regarded as a sort of compound being, made up of a number of distinct parts, each of which is capable, under favorable circumstances, of becoming an independent plant. Every plant, at least all those in cultivation, will be found to be made up of a succession of joints, each consisting of a piece of stem of greater or less length, and a leaf or pair of leaves as the case may be, each leaf having at its base a bud which may or may not be large enough to be noticed. The point at which the leaves are attached is called a *node* or *knot*, and not only do the leaves start from here, but when the stem is buried in the earth, the nodes are the points from which roots most readily start.

Though in some plants they will spring from any part of the stem, in the majority of cases they are only successfully produced from the nodes. We make two sorts of cuttings; those from the ripened wood after the leaves have

fallen, and those in which the plant is still in a growing condition and retains its leaves. The last named are the kind made at the present season. With proper care and treatment each joint of a plant may be made to grow, but in the ordinary way of making cuttings, a shoot containing several joints is taken. To make a cutting a shoot is

GERANIUM CUTTING.

taken from the parent plant, its lower leaves cut off, and set in the ground with one or more knots beneath the surface. In removing the shoot we separate it from its natural source of nutriment, and it has to make new roots before it can begin on its own account as an independent individual. Plants differ very much as to the readiness with which the cuttings will strike root. Some are so difficult in this respect as to require all the skill of the professional propagator, while others will root by being merely placed in the soil. The roots are formed from material contained in the stem

and leaves, and they must be produced before any considerable growth can take place. Evaporation is constantly going on from the leaves, and, in most plants, it is necessary to cover the cuttings with a hand glass or other protection to prevent exhaustion by evaporation. Let us take for example a cutting of a common *Pelargonium* or *Geranium*, as it is commonly called. A shoot of tolerably mature wood is taken, cut at a node or knot, the lower leaves removed, and it is set in the ground as far as the dotted line. In about two weeks, more or less, it will be found that a new growth has commenced between the bark and wood; it appears as a sort of excrescence or *callus* as it is called by the gardeners. This callus is material supplied by the stem and leaves, and forms a sort of bed from which roots will start; it often attains a considerable size, as is shown in the figure, and seems capable of performing the functions of the root, as cuttings that are well callused will often make considerable growth before any roots are pushed out. A cutting which makes a good callus is pretty sure to live. In a rich soil, cuttings are apt to decay before they root, and much better success is usually had if they are planted in a naturally poor soil, or one made so by a large admixture of sand. The professional gardener strikes his cuttings in pure sand, and uses bottom heat; many plants can not be rooted except in this manner, and all are more certainly managed in this way. Many persons not having these appliances, or the skill to use them, are deterred from propagating, thinking that cuttings can only be grown by these means. The fact is that a large share of our shrubs and herbaceous plants can be readily propagated by

means within reach of every one. We have used with great success a common soap box with the bottom knocked out, and a piece of muslin (common cotton cloth) tacked in its place. The cuttings being placed in a sandy soil are covered with this box, which admits sufficient light and retains the moisture. If air is required, the box may be tilted and a brick or other support placed under one side. Where there are hot-beds in use, a frame with the glass coated with whiting or shaded by muslin will be found much more convenient. In this way we have rooted in large quantities and with very little trouble, Fuchsias, Lantanas, Petunias, Verbenas, Cupheas, Ageratums, and a host of other bedding plants, as well as Weigelas, Forsythias, Roses, and numerous other shrubs. The soil should be made very sandy and kept well watered, and in making the cuttings, strong and well or partially hardened shoots should be taken.

THE HOUSEHOLD.

About Naming Children.

A correspondent of the *Agriculturist* writes that several years since he read in some journal a plan for composing proper names of pleasing sound. As near as he can remember, a certain number of consonants were to be placed in one box, and vowels in another, and in some manner specified, these were to be drawn out and a euphonic name would be the result. We never happened to meet with this item, and can therefore say nothing of its feasibility. The subject, however, suggests a few thoughts worthy of consideration. We have known individuals made a laughing stock through life, by the thoughtlessness of their parents in giving them ludicrous names. Who could restrain a smile at hearing announced Mr. Preserved Fish, Mrs. Seedy Brown, Onderdonk Dumper, (sure to be nicknamed "Underdone Dumpling,") or Pullan Wool, known to his neighbors as "Pulled Wool." We have known several instances where persons thus afflicted by the thoughtlessness of their parents, applied to the Legislature for relief. Though apparently a trivial matter, such naming of children is a real cruelty. Constant annoyance from this source is more painful than a serious temporary affliction; almost any one would choose to endure the pain for a few weeks from a broken limb, than be tormented for years by the pricking of a thistle. As a general rule it is not in good taste to give to children the names of distinguished persons. Their station in life may afterward make the contrast ludicrous. Hundreds of names commence with George Washington, and end with Smith, Brown, or Jones, all of them unobjectionable terminations, but made insignificant by the high sounding introduction. It is as if one should erect a splendid gateway at the entrance of a potato patch. Should individuals so named, rise to distinction, they could hardly hope to equal their illustrious namesake, and their fame would thus constantly suffer by comparison. It would be a much less difficult undertaking for the individual to make a new name distinguished.

In naming a child, some reference should be had to the convenience of the appellation: it is a wrong upon a person's associates to require them to waste breath in addressing a person by a long or difficult title. Who could have patience in calling after "Shalmanezzer"? The convenient nickname "Sham" would very soon designate such boy, and accompany him into manhood. The wise man says: "A good name is rather to be chosen than great riches," and although this refers to character, yet it is of great advantage to a person to have a prepossessing name, which will give him at least a favorable announcement in society. No one would wish to be introduced as Judas Iscariot, or Benedict Arnold, and even so small a circumstance as the possession of a pleasant name may open many

avenues to advantage in life. The subject is worthy of thought by those who are fortunate enough to have the bestowment of one of the gifts which must be accepted for life, and which therefore should not be lightly or thoughtlessly disposed of.

The Nonpareil Butter Worker.

The good quality of butter depends upon properly "working" it, as much or more than on any other process in the manufacture. A very small quantity of buttermilk left among butter, will very speedily cause it to become rancid, and then no after treatment can restore its original sweetness. It is also necessary that the salt added to butter should be completely commingled with the whole mass, otherwise it will not be of uniform quality when fresh, and the unsalted portion will soon be spoiled and corrupt the remainder. To properly work butter, it is required that the ladle or other instrument should be brought into contact with every portion of it, and to do this takes no little time, patience, and strength; and as neither of these are found in over quantity among many butter makers, the market is too largely supplied with underworked and inferior butter. We are pleased to notice any improvement that promises to make this labor easier of performance, and thereby renders it more likely that it will be properly done. The engraving at the head of this article represents a recently invented apparatus for this purpose, which has been tested and adopted by some of the leading dairymen in the western part of this State. It consists of a tray, *T*, resting upon a stand or table of suitable height, to which it is attached by a joint, *J*, so that one end may be raised to pour off the buttermilk. A latch, *L*, in front keeps it in place when the worker is being used. The worker, *W*, consists of a ladle mortised into a lever. This lever hangs from the arm, *A*, by a hook, and may be readily detached by bringing it forward and lifting it from the eye in which the hook rests, and only when in this position. The arm, *A*, turns upon a pivot between the two standards, *S*. These standards may be removed if desired, by taking out the key which holds the tenon in the mortise on the sides of this tray. The working of the apparatus will be readily understood by examining the illustration. The operator presses successive portions of the butter under the ladle by means of the lever, and when the butter is crowded back toward the end of the tray, it is readily brought forward to be pressed again by means of the lever and ladle, and is thus repeatedly gone over until all the buttermilk is extracted. The salt is easily worked into

the butter in the same manner. The apparatus in fact enables a person to use lever power in the application of the ordinary hand ladle, and thus greatly diminishes the amount of force required. We consider this arrangement superior to the implement heretofore in use consisting of a roller hinged at one end and working upon a slab, as in the latter case a portion of the butter will be moved along over the surface of the slab with a sliding motion, thereby in some degree destroying the "grain" and making it of a salvy consistence. The above described apparatus is manufactured by Mr. J. P. Corbin, Whitney's Point, Broome Co., N. Y., and sold at about six dollars. They will also probably be on sale at agricultural warehouses, and be advertised accordingly.

New and Improved Milk-Rack.

The illustration given below, represents an improved rack or stand for holding milk, devised and patented by Mr. Robert Cruikshank, Washington Co., N. Y. It consists of eight posts, standing in a slanting position, into which tiers of horizontal slats or bars are inserted

to serve as shelves for supporting the milk pans. There are six tiers of bars on each side, six inches apart. Near the bottom of the posts, inverted conical caps of tin are placed, to prevent rats or mice climbing up to the milk. The racks are made of two sizes; the largest size $5\frac{1}{4}$ by 4 feet at the base, and $5\frac{1}{4}$ by 2 feet at the top, will hold 48 large sized pans; the other 4 by 4 feet at the base, and 4 by 2 feet at the top, will accommodate 36 pans. The advantages claimed for this rack are: The large number of pans of milk which can be accommodated in the space occupied; the pans can be placed on the rack and the milk strained directly into them, thus avoiding danger of spilling; the bars

allow a better circulation of air around the pans than when they are placed on shelves, and consequently the milk cools more quickly and yields an increase of cream. The rack is very simple in construction, and so put together, that the pieces may be easily separated for removing or cleansing. The price of the rack is, largest size \$6, smaller, \$5. It is commended by many prominent dairymen, and appears to be a very desirable arrangement, particularly where space for dairying is limited. It would be just the thing to hold the milk where it is kept in the cellar, as is practised by many who have no building specially devoted to the purpose.

The Rats Have "Skedaddled."

To the Editor of the American Agriculturist:

Yes, they have all gone—where I can not tell—and it was the "Phosphorus Salve" that did it. I bought a box according to your suggestions in the April *Agriculturist*, and used it freely. At first it appeared to agree with the rats, and I concluded that rats which had grown fat on strychnine, arsenic, plaster of paris, and sundry other ingredients,

were proof against even phosphorus. They ate the well buttered (phosphorused) slices of bread with avidity, and I did not see that they diminished in numbers for some time, but when using next the last batch the box contained, I noticed the former dose had not all been eaten, and I fancied the rats were not as plenty. That dose finished them—at least I have not seen or heard of a rat on my premises since, though my neighbor's dog had busy work, about that time in an adjoining yard. I imagined the phosphorus did not kill them outright, as I would see half stupid rats running about, and as they strolled over into the next premises, were an easy prey to a large Newfoundland. If they ever return, I have one more charge left, and if that is not sufficient, Lane, or somebody else will have a customer for another box.

TABITHA.

Moral Education of Children.

To make a child do right is one thing, to teach him to prefer right doing is another, and much more difficult task. The first can be accomplished by rewards and punishments, the latter only by calling into action his own conscience, and accustoming him to obey its requirements. Children trained under the first system are like a clock kept at the right hour by frequently moving the hands; but, as every one knows, a time-piece will only remain correct when the regulator is properly adjusted, and the same is equally true with children; they must not only be governed, but trained to govern themselves. This plain, undeniable statement, explains why so many who have been brought up with the greatest strictness, have, when removed from parental control, and left to themselves, speedily run to ruin. It was like removing the brakes from an engine under a full head of steam.

It is an error to suppose that a child can be taught to love virtue by merely telling him what is right. Some of the most graceless pests in the community have grown up in families where the Bible and the catechism were administered as regularly as the daily meals. Scoffers have pointed to such examples as proof of the worthlessness of the Holy Book, as a guide for life, but this is no more reasonable than to pronounce water of no value because those confined to it in youth, have afterward destroyed themselves by intoxicating drink. Moral truth whether drawn from the Bible or other sources, is valuable above other teaching only in proportion as it is wrought into the life by daily practice. We may safely challenge the world to show an instance of a wicked man, who from childhood was accustomed to guide his life by the precepts of the Bible. The first requisite for right moral training of children is the living example of the parent or teacher. The greater part of education of children whether good or bad is accomplished by this agency. It is useless for a father to chide for anger, and exhibit passion himself when inflicting punishment for the child's display of temper. Every blow given under such circumstances, will confirm the combative tendency of the child. The father who talks about honesty and boasts of sharp bargains, is teaching his child the first principles which may make him an accomplished swindler. The mother who rebukes vanity, and yet indulges in display of dress and ornament, will find that her "actions speak louder than words" in the formation of the character of her daughter. Most of the fixed habits of life, those which determine character and make or unmake the man, are the direct results of imitation while in youth, and they who would be happy in their children, must accustom them to walk side by side with themselves in the ways of virtue.

One of the surest ways to instil and confirm a love of right-doing is to give children an experience of the pleasure of such conduct. For instance, a child is prone to selfishness. Punishment can not drive it out, offered rewards only appeal to and strengthen the motive it is desirable to suppress. Make such a child the almoner of your bounty to some poor neighbor. Let him hear the grateful thanks of the widow for the present received at

his hands, and witness the delight of the scantily clad child to whom he has given some article of clothing. He will participate in the pleasure, and soon be easily induced to secure similar enjoyment for himself, even at the price of self denial, if the parent watches for and makes opportunities for him to exercise his own benevolence. Another powerful but much neglected means of confirming right principles and actions in children, is a readiness to appreciate and mark with approbation their efforts to do right. As long as the child's conduct is unexceptionable, and causes no trouble to the parent, he is too often left unnoticed, but any departure from this course is immediately marked, and perhaps visited with reproaches and punishment. The writer has known children to purposely do wrong in order to attract attention; they were uneasy at being left as mere cyphers, whom nobody cared for. The love of praise is a natural endowment, intended by the Creator to act as one of the strongest incentives to right-doing, and the parent who fails to appeal to it is both unskillful and unwise. Although a child feels an inward satisfaction in good conduct, yet it loves to be appreciated, and when praise is so pleasant to bestow, it is to be wondered at that parents are generally so sparing of commendation. This subject is almost an exhaustless one. Its full elucidation would require volumes, and we can only hope to here present a few leading points to elicit thought in the right direction, and thus aid parents in securing one of the most earnest desires of their lives, the welfare of their children.

A Cutting or Lap Board.

A convenience of this kind was described in the *Agriculturist* Vol. XXI, page 372, (Dec. No.) and highly recommended. A subscriber, A. M. Ward, Hartford Co., Conn., writes that he was constructing such an article, when the paper containing our description arrived, and thinking it superior, he sends an illustrated description for the benefit of our readers. The board is 27 inches long, 18 inches wide, and $\frac{3}{4}$ inch thick; made of white pine, which should be sand-papered smooth, and may be wax polished if desired. Two strips of hard wood are fitted to the ends by tongue and groove, to prevent warping; this is preferable to the use of cleats. Inch marks are made around the three sides, from left to right, which will be very convenient for measuring any work in progress. Additional finish is given by inlaying a $\frac{3}{4}$ inch strip of Boxwood around the edge, to receive these marks. Both sides of the board are finished alike, though this is not essential. The curve in front to receive the body of the person using it is four inches deep. Where much work is required, and the board is to be used by a strong person, Mr. Ward recommends to make it 24 by 36 inches, and the body circle 6 inches deep, and says he prefers to have it square cornered, and without supporting legs. Such a board will cost from 25 cents to \$3, according to material and finish, and it will save many a weary hour of bending over a table in cutting out dresses and other similar work.

COAL OIL FOR BED-BUGS.—One who has tried it says: "Tell the *Agriculturist* readers that if any of them are unfortunately troubled with bed-bugs and think nothing but the spirits of turpentine and nitrate of silver mixture will kill them, they labor under a mistake. Coal oil does it effectually, besides rendering the places where it is used, unpleasant

abodes for new comers. Use a stiff leather or quill and apply to all infected places. The offensive odor in a room soon passes off with free ventilation

For the American Agriculturist.

Convenience of Bags.

In many houses which I have visited, as I have noticed how various articles were "lying around loose" I have wished to say to the good woman of the house, "make a few bags," but as politeness forbade my appearing to notice any want of tidiness, I can only avail myself of the columns of the *Agriculturist* to give a few hints which will be seen by thousands of housekeepers. First there are the shoes and boots of the household, which are usually left standing in closets or corners, where they are liable to be misplaced, and where to me they always look unsightly. Make a bag of dark colored muslin to contain them, and have it hung on a particular nail in the closet, or if there be no room there, in some vacant corner of the bed-room. Always place them there when removed from the feet, and teach the children to do the same (after having thoroughly cleansed them) and they will always be at hand when wanted. Then a bag for each sleeping room to contain soiled clothing for the wash, will contribute much to the tidy appearance of the premises. It is any thing but inviting to see a sleeping room strewn with such articles, and I do not wonder that many families are so sensitive about allowing strangers to inspect their sleeping apartments, when they are so frequently adorned with the garments awaiting wash-day. My opinion is that our rooms should be kept as pleasant for our own occupation as for that of strangers who seldom visit us. I have also found it a great convenience to keep bags for the reception of patches, strings, buttons and all the etcetera which usually encumber the family work basket. It saves no little time to be able to go at once to the proper receptacle for such articles, and I also find that the articles themselves are much more likely to be saved against a time of need, if there be a convenient receptacle at hand to receive them. In the pantry there should be plenty of boxes with close fitting covers, to contain the salt, and various kinds of spices, but if these can not be conveniently obtained, then muslin or paper bags may be made to serve a good purpose, and prevent much inconvenience and waste. I do not believe in having much bag-gage when travelling, with which to annoy gentlemen, hack drivers, and myself, but in housekeeping I have found great saving of time and patience in having an ample supply, and therefore give the hint to those who may need it.

MARTHA.

The Clothes Line.

This is too often a source of annoyance to the "women folks" on washing days. Many a makeshift is resorted to, such as driving nails in the house or some out building, and stretching a line from that to the nearest fence, supporting the line in the middle with a crooked pole. Both nails and hooks are objectionable, on account of rust, and a rain, by shrinking the line, often snaps the nails or hooks and lets the clothes down into the dirt. Every housewife should have a nice "bleaching plot" of grass from 20 to 25 feet square, and around this let the clothes line be stretched on four corner posts. If one cannot afford turned, painted posts, set rough ones with a cross pin near the top to prevent the line from slipping, but the turned posts, with a round head and small neck are much more ornamental. Make them of durable timber.

The writer once fixed a clothes line very conveniently in a carriage house with a hole for the line to pass out, and over a series of wooden pulleys fastened to several posts. The line was coiled around an axle inside, with a crank and stop or ratchet wheel, to wind up by. Putting the rope through the hole and raising the ratchet stop, the end was passed through the several pulleys, and

finally fastened to the last pole. The poles may be in a straight line or around a square, as desirable. Having fastened the end securely, put down the stop to the ratchet wheel and wind up tight. To take in the line, simply untie the further end, and wind up with the crank inside. Where no building is convenient, a box containing the wheel or axle, with a water tight, projecting roof may be set upon a post, and will answer the same purpose. An illustration of such an apparatus was published in the *Agriculturist*, vol. xx, page 277, (Sept. No.)

Value of Illuminating Oils.

A few years have shown a wonderful change in our methods of illuminations. Outside of cities and towns where gas is furnished, we, as a general thing, depend upon some form of mineral oil. Under the names of Kerosene, Carbon oil, etc., a great number of products are sold and used, and as these are of various prices, it is a matter of interest to know which of them gives the most light for the money. The cheapest oil does not of necessity give the cheapest light, and unfortunately there is no ready way in which people in general can settle this point for themselves. The only way in which the relative value of two specimens of oil can be determined, is by ascertaining the quantity required to produce an equal amount of light. The following is the plan used by those who practically test these oils, and may be practised by those who have the means, and are curious in such matters: Take two lamps, the wicks of which are of equal size, place them upon a table which stands a few feet from the wall, set a broom or stick against the edge of the table nearest the wall, in such a way that the lamps will cast a shadow of the broom handle or stick upon the wall. The lamps being at equal distances from the object, the strongest flame will cast the strongest shadow upon the wall; turn down or raise the wicks until both lamps throw shadows of equal strength. The lamps being weighed at the beginning of the experiment, and being so adjusted that they give an equal amount of light as determined by the shadows of the stick, are allowed to burn for some hours and then weighed again. Of course the lamp which has lost least, contains oil of the greatest illuminating power.

Hints for the Sick Room.

The body enfeebled by disease is disturbed by influences so slight as to be unnoticed by a person in health, and hence there is much suffering in the sick room, which might be alleviated by attention to a few particulars which are often overlooked. The invalid should occupy the most capacious, airy and cheerful apartment in the house, if possible away from the noise made by household operations, and where the odors from cooking can be excluded. The smell of food is nauseating in many instances, and in others it stimulates a craving which it would be improper to gratify. Usually there is too great dread of fresh air for the sick. We have seen every crack in the doors and windows carefully stopped, when the hurried breathing, flushed cheeks and uneasy restlessness of the fevered sufferer plainly showed that the disease was aggravated by breathing the poisoned atmosphere. Draughts of air directly upon the person are to be avoided, but the sick, even more than those in health, require abundance of fresh pure air.

Plain ceilings are always preferable to papered walls for sleeping rooms, and especially for the sick room. The eye of the nervous invalid will be fatigued by following the figures of the paper, and very often the disturbed imagination of the sufferer will see in them the most grotesque and hideous forms. The room should be carpeted, or in summer it may be covered with India matting, which gives the appearance of coolness. The furniture should be convenient without superfluous articles, to avoid much dusting and arranging. Medicines and other articles incident to sickness should be kept out of sight; it is almost enough to make a well person

sick to see a long array of bottles, tea eggs, etc., upon the mantel shelf, or on chairs about the room.

Kind friends are frequently a great hindrance to convalescence of a patient. They want to see him, to express their sympathy, cheer him up, or perhaps to recommend some new remedy. Very few if any visits should be allowed in severe cases of indisposition, and none except with the consent of the attending physician. Such calls should be made in the morning, before the patient is fatigued, and the visitor should introduce only pleasant topics of conversation if talking be allowable. None but the most thoughtless would remark upon the ill appearance of the sick person, or endeavor to entertain him with an account of the visitor's sufferings under similar circumstances. The nurse especially, should maintain a quiet but cheerful demeanor. All unnecessary motions, such as rocking in the chair, trotting with the foot, and noise of rattling paper, coughing, blowing the nose, etc., should be avoided. The aim should be in every way to administer to the comfort of the sufferer, and thus keep him in the most favorable circumstances for recovery.

Aerated or Unfermented Bread.

A friend asks us what is the character of this bread which is so generally sold in cities. The Aerated bread is made by machinery. The dough of flour, water, and salt is worked in a cylinder in such a manner that the carbonic acid gas which the cylinder contains, is completely incorporated with it. The dough is then baked, and the gas which is entangled with it, expands by the heat and renders the bread very light. To those who like unfermented bread this is very palatable, though it is not at all to our taste, any more than the bread raised by the use of soda and cream of tartar. In this as in the aerated bread, the lightness is obtained without any change in the flour. When bread is fermented by means of yeast or leaven, the flour undergoes a change and gives off carbonic acid, and if the fermentation is arrested at the proper point by baking, the resulting bread has a sweetness and a peculiar flavor which all the substitutes lack. It is only from the fact that bread making is a rare accomplishment, that these substitutes are welcomed, they being preferred to poorly made fermented bread. In half the families where yeast bread is used, it is allowed to ferment until it gets sour, and then saleratus or soda added to correct the acidity, making a compound unfit to eat. We entreat those mothers who know how to make good bread, to teach their daughters how to do it, else in a few generations bread making will be one of the lost arts.

Beef Tea.

Nothing is more nourishing than properly prepared beef tea, and it is usually acceptable to the convalescent. The lives of many of our wounded might be saved, could they be sustained by this concentrated nutriment. To make it in perfection, select perfectly lean beef, cut it into small pieces, rejecting every particle of fat; put the meat into a bottle, a common junk bottle will do, set it into a kettle of cold water, put it on the fire and let the water boil for two hours. The juice of the meat will be extracted by this method in a very concentrated form. It may then be strained off and seasoned with salt, and other condiments to suit the taste or condition of the patient.

Plants in Sleeping Rooms.

A lady subscriber wishes to know if it is injurious to sleep in a room where plants are kept. Plants in the absence of sunlight give off a small amount of carbonic acid, and any considerable amount of this renders the air unfit for breathing. If the sleeping room is as well ventilated as every room of the kind ought to be, we should not apprehend

any danger. A single additional person or child even, would tend to vitiate the air vastly more than the ordinary number of plants kept in rooms.

Sealing Fruit Bottles with Putty.

J. C. Emory, Luzerne Co., Pa., writes to the *Agriculturist* that having tried the plan recommended in this journal of sealing the mouths of fruit bottles with a cement of rosin and tallow, he found it sticky and troublesome to manage, and hit upon the following substitute. From the small patty pans he cut a circular piece just large enough to enter the mouth of the jar and rest upon the shoulder. When the fruit was prepared, one of these tin covers was introduced, and confined in its place by a roll of putty about the size of a pipe-stem, pressed down tight around the edge of the tin and against the sides of the neck of the bottle. He found this method entirely satisfactory, as the fruit was well preserved, and it was much more expeditious and less troublesome than cementing with the ordinary preparation. [We doubt the general utility of this. The putty would not be strong enough to resist a little outward pressure that may chance to result from slight fermentation. The "Baker Jar" (made by Bodine) saves all cementing, and as it may be used year after year, it is cheaper in the end.—Ed.]

Hints on Cooking, etc.

Green Tomato Pickle.—Contributed to the *Agriculturist* by Mrs. Mary A. G. Weeks, Essex Co., N. J.: Slice the tomatoes, with one-eighth to one-sixth as many onions: lay them down in jars, sprinkling in fine salt at the rate of about an ordinary teacupful to 8 gallons of the sliced fruit. Let them stand over night, drain; add a few green cayenne pepper pods and nasturtiums. Chop until not larger than grains of corn; drain thoroughly; pack in jars, adding white mustard seed, unground cinnamon, and bruised (not ground) clover. Pour on cold vinegar, cover with a plate within the jar, to keep the pickle under the vinegar.

Pickled Cabbage.—Contributed to the *Agriculturist* by "Aunt Mary," Rochester, N. Y. Cut the heads into quarters, let them stand a short time in cold water. Chop them fine, together with nice celery, sufficient to season it. Fill small jars or glass cans, with these ingredients; make a sweet pickle of molasses and vinegar, season with plenty of red pepper and cinnamon, and other spices to the taste, boil all together a few moments and pour over the cabbage while hot. Cork the cans and place in the cellar. This should not be eaten under three or four weeks. It is a nice relish at any time after sufficient pickling, with cold meats, etc.

To Pickle Ripe Cucumbers.—Contributed to the *Agriculturist* by "Olivia." Pare the fruit, and cut it to any shape that may be fancied, and let it soak in salt water forty eight hours; then boil in pure water until quite tender. Thrust bits of cinnamon, mace, and cloves into each piece of fruit, pack in an earthen jar, and fill with boiling vinegar sweetened to the taste.

Hotch Potch.—Take any cold meat, chop or slice fine, season with salt and pepper or sage, if liked. Add to this half as much stale bread, or potatoes that have been hoiled. Stir the whole together and enclose it in a crust as for chicken pie, and put up the same way. Bake one half hour.

Home-made Hard Soap.—The following directions are communicated to the *American Agriculturist*, by Mrs. Abraham Brower, of N. Y. City: Boil together 9 quarts of water, 5 lbs., of clean grease, 1 tablespoonful of salt, and 1 lb. "Concentrated Lye," to be had at any large drug store. Continue to boil until a little tried on a cool plate is found to be sufficiently hard. The above makes about 18 pounds of good hard soap. It can be cooled over night in a wooden tub or other vessel, then cut into cakes of convenient size.

A Lesson from the Wheat Field.

The lad in the picture is learning a lesson he will not soon forget. It is worthy to be remembered by every boy and girl, and would do no harm to a good many grown people. This boy had been walking with his father in the village street, where he was much pleased with the looks of a finely dressed young man who was strutting about with a consequential air, swinging a cane, and carrying his head very high, as though he owned half the place, and knew more than all the people in it. When the boy's father stopped to talk with an ordinary looking man, that was passing thoughtfully along with his head down, the little fellow grew quite impatient, and afterward said, "That man don't look smart, I'd rather be like the gentleman we saw a little while ago." They strolled out to the fields, and presently the father stopped near a plot of wheat, and requested his son to examine the heads on the different stalks. He soon found that those which stood upright were empty and worthless, while those filled with grain bent down toward the earth. "There," said the father "is a picture of the men you met this morning; the one who carried his head so high, was a foppish young clerk who spends all his earnings for dress; the other was Judge C., one of the most learned and respected men in the community." "You mean he is headed out well," replied the boy, for he understood the lesson and felt its force. "Yes," replied the father, "the more a man knows, the more humble he is likely to be, for the more he sees how many things there are yet to learn; while the ignorant are usually conceited, and carrying a high head is almost a certain sign there is little in it. We trust our young readers will strive to be "well headed out," as the boy expressed it, and that if tempted to show off how much they know, they will remember the lesson of the wheat-ears.

Coaxing Out Whiskers.

A correspondent of the *Agriculturist* relates the following: A young man who had recently entered a large village store as clerk, was very desirous to appear well in the eyes of the ladies. Being very vain, he naturally supposed he could best gain their attentions by adding to his personal attractions, and accordingly he was in great haste to raise a moustache and whiskers, which he thought would make him altogether irresistible. One of his fellow clerks, a mischievous wag to whom he had told his wishes, resolved to have some sport with him. Accordingly he informed the beardless youth that a friend of his, a physician, could furnish a preparation which would bring out the hair in an incredibly short space of time. The young man had seen advertisements of such compounds, and suspecting no trick, eagerly asked for a bottle of the mixture. A few days afterward, his companion brought him a vial, with directions to apply the contents carefully wherever he wanted hair to grow, but by no means to touch any other place with it, as it was very powerful. Upon retiring at night the young man gave his upper lip and chin a good dressing with the liquid, and turned in to dream of a splendid beard. Of course in the morning he at once looked at the glass to see the effect produced. But one look was enough, his lip and chin were stained black as a negro's, with a solution of nitrate of silver. In vain he washed and scrubbed; the color was fixed, and could only wear off. To add to his dismay, a loud shout greeted his ears, and he saw all his fellow clerks, who had been let into the secret, almost convulsed with laughter. Hastily dressing himself, he muffled his face, rushed to his distant home,

and concealed himself until his face resumed its natural color. This was a severe and unwarrantable joke, but it partially cured the young man of his silly ideas, and on the whole was a benefit to him. Whenever he assumed any airs, his father had only to ask if his whiskers were yet grown, to bring him to his senses.

Sagacity of a King Bird.

The writer was once walking near a cliff which overhung the sea, when a young King Bird (*Tyrannus Intrepidus*) started from the fence near by. The wind was blowing hard at the time, and I at once saw that his youthful wings were unaccustomed to buffet the fierceness of the blast. He arose easily as a kite would ascend. But when he had attained a few feet, the difficulty was to drop again to the earth. Indeed all his efforts only seemed to carry him higher. The wind lifted him up, until he was unable to fly against it. For a few moments he stood almost still in the air. His greatest exertions only serving to make him hold his own. Soon his strength failed and he gradually fell away as the wind bore him off toward the water. I watched, unable to help him, and trembling for his approaching fall. I knew that, like a helpless ship, he would soon be engulfed in the ocean. Faster and faster he was floating toward the deep. He had almost ceased to struggle, when all at once, as though another bird had fallen from heaven there appeared two, one behind him, beating him down with her wings. The mother bird had seen her offspring's danger, and coming to his aid, flapped him down with her wings, when only a few yards of earth separated him from the waters beneath. I breathed freer when I saw him safe, and left the mother to rejoice with her fledgling, thinking now often was a similar scene enacted in our own childhood.

A. H. G.

Boys' and Girls' Garden—No. 5.

In our last talk with our young friends we attempted to give them a general idea of the parts of the flower and their uses. As the space was limited, we gave a mere outline without going very much into particulars, knowing that we should be obliged to go over the ground again. It was stated that the Flax flower, which we took for our illustration, had two sets of leaves, making together what are called floral envelopes, the outside one being the calyx, and the inner one the corolla. The calyx in the Flax is made up of little green leaves called sepals. All the parts of the flower are to be considered as leaves adapted to serve a particular purpose. Some of the parts look very much unlike leaves; but having

Fig. 20.—FLAX.

seen how different from the common leaves are the cotyledons or seed leaves, you will have no difficulty in understanding that the leaf may differ still more widely from its ordinary shape to serve the purposes of the flower. The parts of the calyx are so like common leaves that it is easy to see what their real nature is. Next within the calyx is the corolla, which, in the Flax, consists of five distinct petals. These are usually of some other color than green, and are of a different shape, and of much more delicate texture than ordinary leaves. Still the botanist looks upon the petals as leaves in a peculiar condition, and the fact that flowers are sometimes found with green leaves in the place of petals, shows that this view is correct. If you pull the Flax flower apart you will find that the petals are all separate and distinct, but if you take the flower of the Tomato (fig. 21), you will not be able to pull off any separate petals. You will see that this flower differs from the Flax in having the petals united or grown together part way up. When the flower of the Tomato is pulled apart, the corolla comes off in one piece. We have taken the Flax as a starting point from which to illustrate the structure of the flowers in general. By altering the shape of the petals, making them broader or narrower, blunt or pointed, a great many shapes would be got from a flower

Fig. 21.—TOMATO.

in other respects like the Flax. When the petals are united at the edges, as in the Tomato, we get other kinds of flowers. This union of the petals may extend only part of the way as shown in the Tomato, or they may be united for their whole length as is seen in the Morning Glory (fig. 22). The corolla of the Morning Glory is all in one piece, and looks very different from that of the Flax. By carefully examining the corolla of the Morning Glory, you will see five lines or seams, showing that the corolla is of five parts which are all united together by their edges in one piece. Flowers which like the Tomato and Morning Glory, have the petals more or less united, are called *mono-petalous*, meaning one petaled, or rather that the petals from being joined together appear as one, while those which have the petals separate like the Flax, are called *poly-petalous*, or many petaled. The flower of the Pea looks very different from that of the Flax, and at first sight there does not seem to be much similarity between them; it is a very irregular looking flower, but when we pick it to pieces we see that there are five parts to the corolla, but they are of such different shape and size as to give the flower a very odd appearance. Fig. 24, represents the flower of the Pea. Beginning at the upper side of the flower, there is a very large petal, which is so much bigger than the others that it seems to make up the largest part of the flower. In flowers which are made after the same pattern as that

Fig. 22.—MORNING GLORY.

of the Pea, this petal is called the *banner*. Just below this and placed at the right and left are two smaller petals which are called *wings*, and between the wings is a rounded body looking something like the prow of a boat, and for this reason is named the *keel*. If the keel is removed and opened it is found to be made of two petals joined by their edges, but separated below as they are shown in fig. 23. We have illustrated four flowers widely differing in appearance—the Flax, Tomato, Morning Glory, and Pea—yet they are all made upon the same plan. The parts of the corolla are in fives, (except the Tomato which has from 5 to 10 parts) and however they may be disguised by uniting with one another, or by having some parts larger, or of differing shapes, the general plan is the same. Though we have shown the variations in only four flowers, any one who has thoroughly studied the structure of these, will have but little difficulty in making out the nature of all other flowers. The parts of the Flax are in fives, which is perhaps the most common number, but other flowers are in fours or threes. When we look around among flowers, we find an infinite variety, and it would seem at first sight that they are made upon widely different plans, but with the Flax flower in view, and the variations that have been shown, we think you will have little difficulty in understanding the structure of all single flowers. We shall speak of the double ones at another time. You have learned where to look

Fig. 23.—PEA BLOSSOM SEPARATED.

of the Pea, this petal is called the *banner*. Just below this and placed at the right and left are two smaller petals which are called *wings*, and between the wings is a rounded body looking something like the prow of a boat, and for this reason is named the *keel*. If the keel is removed and opened it is found to be made of two petals joined by their edges, but separated below as they are shown in fig. 23. We have illustrated four flowers widely differing in appearance—the Flax, Tomato, Morning Glory, and Pea—yet they are all made upon the same plan. The parts of the corolla are in fives, (except the Tomato which has from 5 to 10 parts) and however they may be disguised by uniting with one another, or by having some parts larger, or of differing shapes, the general plan is the same. Though we have shown the variations in only four flowers, any one who has thoroughly studied the structure of these, will have but little difficulty in making out the nature of all other flowers. The parts of the Flax are in fives, which is perhaps the most common number, but other flowers are in fours or threes. When we look around among flowers, we find an infinite variety, and it would seem at first sight that they are made upon widely different plans, but with the Flax flower in view, and the variations that have been shown, we think you will have little difficulty in understanding the structure of all single flowers. We shall speak of the double ones at another time. You have learned where to look

Fig. 24.—PEA BLOSSOM.

for the calyx and corolla, and have seen that the corolla can be united in one piece as in the Tomato and Morning Glory, or that its parts may be very unequal in size, and two of them be united, as in the Pea. By following out these changes, a great variety of forms can be produced. This study of shapes is called *morphology*. You have seen a little of the morphology of leaves, and have had illustrations of leaves which though differing widely in form, still performed the same office. In the flowers spoken of above, you have seen how the shape of the parts may be changed and yet they still occupy the same relative position and serve the same purpose. This is one of the most interesting things in the study of plants; to see how wonderfully the parts may be varied and yet be essentially the same. Leaves might have been all alike and the flowers all the same shape, and the great purpose of vegetation would have gone on the same. It would seem that the Creator had introduced this wonderful variety merely to please our senses and gratify the love of the beautiful that he has made a part of our nature. When, after admiring flowers we begin to study and examine them, we are still more impressed with the skill which planned them, and wonder at the infinite variety that can be wrought in a few simple materials. We see illustrations of morphology in the common objects about us. The log cabin is not essentially different from the costly dwelling; both have four walls and a roof, and these differ in shape and materials in accordance with the wants and means of the owner. Our articles of dress are changed in fashion every year; the coat, hat or gown of five years ago looks odd to us now, yet it is the same as worn at present, only differing in the shape of its parts. The changes which a hat assumes illustrate very strikingly the subject of morphology. The simplest form of hat is a mere bag with a string around it to fit it to the

Fig. 25.—CHANGE OF THE HAT.

head of the wearer, as shown at A. This would answer the first use of a hat: to keep the head warm. By turning out the portion below the band as shown at B, we get a brim which also shades the face, and here we have all that is required in this article of dress. To please the fancy we press out the crown and stiffen it so as to take the common shape C. By slipping the band further up, the brim is widened and the crown shortened as shown at D. If the crown is spread out above, we get the "bell crown" E, worn by our grandfathers. The cap, one form of which is shown at F, is only a low crowned hat with the greater portion of the brim cut away, leaving the visor or plate. These illustrations might be carried on to a much greater extent, so as to show that every style was

Fig. 26.—CHANGE OF THE HAT.

a simple modification of the simple hat shown at A. Our original hat is capable of other changes: lay it on its side, untie the bow of the band, and cut out an opening for the neck and you have G, a very rude form of a bonnet; the ends of the band form the string which will serve to tie under the chin. If the crown is swelled out as at H, we get a not unusual style of bonnet. By varying the shape of the crown we produce the shape shown at I, which is a style worn within our recollection, and by reducing the crown and swelling the front the more modern styles J, K, and L, are obtained. If you have had any amusement in tracing out these shapes of the hat, recollect that we have given them only to help you to trace out in the various single flowers you meet, the variations from the Flax flower which was taken as a pattern or starting point.

HE KNOWS THE REST.—A little girl was carried to her room at night and laid upon her bed, while half asleep.

Upon being reminded that she ought not to forget her prayers, she half opened her eyes and dreamily murmured, "Now I lay me down to sleep, I pray the Lord"—and then adding "He knows the rest," she sank upon her pillow, in His watchful care who "giveth his beloved sleep." It was a fine illustration of faith.

New Puzzles to be Answered.

No. 47. *Illustrated Rebus.* Something often forgotten.

No. 48. *Arithmetical Problem.* Contributed to the *Agriculturist* by J. McCulloch, Logan Co., O. A person has a distance of 46 2-13 miles to go and return, and has but 3 hours to do it; he travels 60 per cent. faster in going than returning. What rates per hour does he travel in going and returning?

No. 49. *Arithmetical Problem,* by the same contributor. Two men, A and B, worked separately on a job; first A worked $\frac{2}{3}$ of the time that B would have taken to do the whole job, then B finished the whole job; now had they both worked together, it would have been done two days sooner, and A would have done only half what he left for B. In what time could each do the job separately?

Answers to Problems and Puzzles.

Answers to Problems and Puzzles in July number, (page 217.) No. 44. *Illustrated Rebus.* "A w R knot the vest hat dogs bark at," or, "All are not thieves that dogs bark at." No. 45. *Curious Sentence.* Wright, write right. No. 46. *Arithmetical Problem.* Answer: A should receive \$171 99-331, B should have \$98 232-331.

The following have sent in correct answers; the numbers indicate the problems, etc., answered by each: Thos. R. Newton, 40, 43; T. R. S., 40, 41, 43; Ruel L. Smith, 41; Charles Munger, 40, 41; Fred. E. Parker, 41; Jessie E. Bradley, 41, 43; C. A. K., 41, 42; Eleanor H. Risdon, 40, 41, 43; H. S. Anderson, 44; Thomas S. Monre, 44; C. Coggeshall, 43; S. Emma Barker, 46; Annie M. Low, 44; J. W. English, 44, 46; Lizzie S. Bundy, 44, 45, 46; B. B. Baum, 44; Sarah Roley, 44; James M. Cox, 44, 45, 46; Luey H. Lazear, 44; Mary Ida Lazear, 40, 41, 43; James Dilts, 44, 45; George A. Goodrich, 44, 45; I. Hoffman, 44; Wirt C. Williams, 44.

Editorial Correspondence.

Gettysburg Battle-Field.

Gettysburg, Pa., Thursday, July 7, 1863.

On learning of the great battles of July 1, 2, and 3, I determined to abbreviate my agricultural tour, and hasten here to see with my own eyes, the field of the greatest conflict that has yet occurred on this Continent, and one which has seldom been equalled in the Old World during modern times. In its results, it is scarcely less important than any battle in the world's history. Just a year ago I passed over the field of Waterloo in Belgium, where the armies of Europe settled the fate of empires and the form of governments for ages to come. As I now write, my eye takes in at a glance the wide field where, within a week past, nearly or quite two hundred thousand men were engaged in mortal strife, upon the result of which, it would now seem, is to depend the future of the people of this western world. Had the scales turned decisively the other way, it would have materially changed the style of American society and civilization in this country. If, as it is hoped, the victory at the close of the contest last Friday morning, is the turning point of the war that has desolated our country for more than two years past, this field will indeed be memorable in future history. Emotions too deep for utterance, fill my mind as I look over the surrounding valley and the dozen hills in sight, almost every foot of which was but last week trodden by armed hosts. I will not attempt to describe the scene or the occurrences, but will jot down a few items that may interest the readers of the *American Agriculturist*, so many of whom had sons, or brothers, or husbands, or fathers, among the heroes who fought and perhaps bled and died here, and all of whom are so intensely interested in the consequences of the contest.

I arrived here at daylight on Tuesday morning, in company with some of the delegates of the "Christian Commission." We immediately went to the largest hospital camp, that of the Second Army Corps, which is located some $3\frac{1}{2}$ miles south of the village—the wounded of this corps having been taken to that point during the progress of the battle, to be out of reach of the flying missiles of death. The camps of the other corps are

similarly located at different points. Very few of the thousands of visitors constantly arriving and departing, find their way to these camps, where are to be seen the real evidences and the more marked results of the strife. The main army has followed in pursuit of the retreating enemy; the driving rain of yesterday has smoothed the surface of the ground that was disfigured by the plowing shot and shell, and by cannon-wheels and horses' hoofs. With here and there an exception, the dead lie covered beneath the ground where they fell, and the rain has flattened the hastily-made graves of the enemy, so that near observation is required to find them, though numbering many hundreds, if not thousands, scattered all over an area of five miles long, and nearly two miles wide—sometimes in groups of three, five, and up to fifty, but oftener one in a place. The graves of Union soldiers are generally banked up, and are mostly marked by a board, giving the name, company, regiment, and State. This enables friends to find their remains, and the work of removal has already begun. The graves are in the fields, on the hillocks, in the groves, etc., and one sees but a few from any single stand-point. The most visible signs of the contest are the demolished fences over a thousand or more acres; the hastily-thrown-up breastworks (of rails, stones, and earth, here in 20-foot semicircles, there in long lines; yonder in little mounds as rifle-pits;) the thousands upon thousands of guns, military equipments, and clothing thrown away in flight, or dropped by killed or wounded soldiers, and the solid cannon-balls, or exploded or unexploded shells that strew the ground. The rain has entirely washed away all blood, and covered most of the smaller missiles, though half a million cartridges and musket-balls could doubtless be gathered. In a dozen groves, there is hardly a tree that is not scarred by bullets or cannon-balls, while from many, a branch or two is lopped off, or the trunk is severed at some point above the ground. The most visible effects, however, are the unburied carcasses of horses, the bodies swelled to double size, and already white with maggots. From the sight and smell of these, one can hardly escape, go where he will on over a thousand acres. At one point, close by the little board dwelling where Gen. Meade had his headquarters at first, I counted fifty dead horses within the space of half an acre. The building itself is shattered in a dozen places by pieces of shell. A looking-glass hanging in front of the General's writing-desk, was struck by a shell fragment. A piece of this glass is among the few mementoes I have picked up. At the tower end of a gully, I noticed at least three wagon-loads of clothing, blankets, cartridge-boxes, scabbards, etc., that had been washed there by the rain-torrents that poured down all Wednesday forenoon with a violence never before known by the oldest citizen.

But all the above are feeble evidences of war, as compared with the camps. I visited and worked in three. I went to look at them, but there were too many suffering ones, friends and enemies, needing a cooling or stimulating draught, a little bread, or a change of position, to allow of time spent in gratifying curiosity, and I gladly joined hands with my brother agricultural editor, Mr. Spangler, and with the few members of the Christian Commission who had found their way through mud and rain, bearing food, raiment, stimulants, etc. No one who could witness the relief afforded by a warm, clean garment, a taste of wine, brandy, or extract of ginger, would ever after give with a sparing hand, or indulge his own appetite for luxuries, while soldiers are lying wounded in hospitals, and camps. In the 2nd Corps camp alone, we found nearly or quite three thousand wounded men, about one third of them of the enemy, who left behind thousands upon thousands of the worst wounded, but left no surgeons, and none of their more slightly injured, who could have aided the others. Our surgeons were hard at work, and had attended to most of their own men, but many of the enemy were still lying on the ground in the rain, their wounds untouched, five days after the battle. Their own destruction of roads and bridges rendered it utterly impossible to get in supplies or nurses for them at once. I am glad to say, that yesterday afternoon, and this morning, hundreds of men, and tons of supplies have arrived from the Christian Commission, the Sanitary Commission, the Firemen, and Adams' Express Commission of Baltimore, and many other city and town associations, so that at this hour, every man, friend or enemy, is being cared for. But oh! the sad spectacle I witnessed yesterday morning as I went round among three thousand wounded men, giving a cup of water here, a stimulating draught there, a piece of soft bread to this one, some tanna to that one; now shifting the position of one who had grown stiff from lying days and nights in the same place, and now helping to move another from a pool of water gathering around him. The broken and shattered limbs, the torn bodies, the busy surgeons in that grave! The scene will never fade from my memory. I have often read of these things but no pen can give even a faint idea of the reality. I spent my time mainly with the fallen enemy, for these were most

in need. How their sufferings wipe out the remotest feeling of enmity! Most of them were from North Carolina, and in bitter tones did they complain of those who had brought on this war, and forced them to take part in a strife for which they had no heart—a strife to break up a Union which they loved.

Exhausted by labors in which I had been stimulated to exertion far beyond ordinary endurance, and relieved by hundreds of fresh hands, I left the camp to-day, and have this afternoon walked and ridden around the battle fields to gain some idea of the contest. I have not time, strength, or space for more than a brief description.

I write sitting upon a marble shaft broken by a cannon ball in the cemetery, on a hill, the summit of which is about on a level with the tops of the church steeples in the village of Gettysburg, 75 to 100 rods north of me. A gentle valley about a mile wide comes in from the east, bends around north of the village, and runs west, then southwest, and nearly south. High ground extends from this cemetery to the southwest, and a low broad ridge gently slopes off into the valley, and terminates in a bluff of bare rocks facing the west, beyond which is a high round-topped hill. Back of me (south) is low ground, followed by alternate ridges and valleys. On the right (southeast) are several hills partly wooded, with hollows between. Directly east is the valley first described. A hundred rods or so southwest of me is the little house at first occupied by Gen. Meade, with a grove on this side. Just back of my left is another little grove. Away beyond the valley, on the north, northeast, northwest, and west, are a succession of elevated knolls, forming almost a continuous ridge. Woods upon some of these, and in the hollows beyond, form apparently a continuous grove, which screened the movements of the enemy in transferring corps and brigades, from wing to wing. The low hills around the northern side of the whole semi-circle were occupied by the batteries of the enemies' cannon, which sometimes concentrated their entire fire on the spot where I sit, and the shells went over and across, often falling in the valleys for a mile or two south. Their effects are seen in the dead horses and the scattered graves. Part of our troops were placed upon this point (Cemetery Hill) and along the high ground a mile southeast, and three miles or so southwest, while others were in the valleys to the south, and were moved to the left or right as required by the exigencies of the battle.

The first day (Wednesday) Gen. Reynolds' Corps marched through the village, to the hills northwest, where they discovered the enemy before concealed by the hills and woods. After a sharp contest this Corps were overwhelmed, and retreated through the village to the Cemetery Hill. During the night the rest of our army came up from the south, and the balance of the enemy came in from Chambersburg, at the northwest, Carlisle at the north, and York at the northeast. All day Thursday and Friday, was spent in attempting to drive our men from their position, or break through their lines. More than a hundred cannon upon the circle of hills, with occasional intermission sent a shower of shells over the valley. Now on the right, and now on the left, large bodies of men would come dashing through the valley, and attempt to force their way through our ranks. The moment they appeared in sight, our shells began to fall upon them; when from $\frac{1}{2}$ to $\frac{3}{4}$ mile distant, canister shot mowed down their fearful swarms; when almost up to the cannon, long lines of men rose from behind stone fences, or extemporized breast-works of rails and earth two to three feet high, and rained in upon them myriads of minie balls, and in every case the shattered columns though almost up to our men, were sent flying back through the valley in disorder. Sometimes they threw into confusion and retreat a small body of our men advanced far into the foreground, but ere they reached the established lines, the quick eye of the General had observed it, and a reserved force was sent forward, who had been until then concealed in the low ground or woods at the rear (south) engaged in the other wing, and these turned back the tide. At the left, where are two groves, the battle moved back and forth several times. A farm-house and barn at this point are shattered by shells and canister shot, from garret to cellar. (I have in my pocket a canister shot that went through the door, through a partition, and lodged in the plastering on the opposite side of the parlor.) Thirty graves of the enemy's officers are seen near the barn, marked by head-boards. In a wheat field close to the woods out of which our men emerged in one of these counter charges, I counted on a space less than 100 feet square, forty-nine bodies of the enemy, untarried two hours ago. The grand final attempt was made on Friday toward evening. A body of men (in solid ranks as far as the eye could see, says a slightly wounded soldier by my side) came driving across the plain or valley a little west of the village, on our left center. They were determined to break through by force of numbers. But, as in other cases, they were hurled back, thousands of them falling dead or wounded, (only one out of eight or ten who are hit, is killed). In the confusion thus produced, a column of

our men concealed in a hollow, and by bushes a little further south, closed in around some 3000 of the broken mass, and took them prisoners. The rest retired again over the valley, and thus ended the three days' strife. With a bold show in front, the enemy retreated, concealed by the hills and woods, on Saturday and through the night. As our own men entered upon the vacated ground, the wounded enemy were found in fields and groves for miles away, and they are yet being found and brought in. The churches and almost every house in the village are filled with wounded, in addition to the hospital camps, though none of the latter are so large as that of the 2nd Corps above referred to. Strange to say, though tens of thousands of missiles were hurled over and around the village, very few houses show any marks, and the inhabitants in part remained in safety, as all could have done.

But I must close, for I have already provided for filling all the spare columns. As I sit here and take in the field of contest at a glance, and think of the results to flow from it in the long future, I can not refrain from sending these few items to our readers. It were worth a long pilgrimage to come here, not to gather relics, but to contemplate on the ground itself the stirring events which have so recently transpired on this Waterloo of America, this triumphant battle field of American Freedom.

Business Notices.

Eighty Cents a Line of space.

Pure and Economical Articles for Family Use.

Pyle's Cream Tartar,
Pyle's Saleratus,
Pyle's Baking Soda,
Pyle's O. K. Soap.

Housekeepers will find these articles reliable, and the cheapest in the end. Sold by Grocers everywhere.

JAMES PYLE, Manufacturer,

350 Washington-street, corner Franklin, New-York.

The Avoidable Causes of Disease,

Insanity, and Deformity, Marriage, &c., by John Ellis, M. D.—two volumes in one—is the most interesting and useful book of the age, and every farmer should have it; for the health and lives of his wife and children are of more consequence than horses, cattle, sheep and farmers. This volume will be sent by mail, postage paid, for \$1.25. Address Dr. John Ellis, 47 West 29th-street, New-York. Dealers may apply to the Publishers.

MASON, BROTHERS,
5 & 7 Mercer-street, New-York.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$3.25, or with six beautiful mounted objects for \$5. Address HENRY CRAIG, 180 Centre-st., New-York. A liberal discount to the trade.

Lands—To All Wanting Farms.

Large and thriving settlement of Vineland, mild climate, 30 miles south of Philadelphia, by railroad; rich soil; fine crops; twenty acre tracts, at from \$15 to \$20 per acre; payable within four years. Good business openings; good society. Hundreds are settling and making improvements. Apply to CHAS. K. LANDIS, Postmaster, Vineland, Cumberland County, N. J. Letters answered. Papers containing full information sent free.

Business in all articles of Domestic produce has been restricted, during the past month. Lee's invasion of Maryland and Pennsylvania, early in the month, occasioned great alarm, and a partial suspension of all other than military operations. His speedy defeat by Meade, and the glorious news of the capture of Vicksburg, Port Hudson, and Chattanooga, restored public confidence. Gold accordingly fell off rapidly, closing as low as 125 1/2 c. @ 126 c., or at the reduced premium of 25 1/2 c. @ 26 c. per cent. This sharp reaction of course brought about a corresponding decline in the market value of most kinds of produce, particularly Breadstuffs; and made holders very eager to dispose of their supplies, rather than take the risks of the future. Buyers, however, have been reluctant to purchase freely, especially for export, owing to the great depression in the market for Sterling Exchange Bills, which are usually governed by the price of Gold. At present, all parties are sorely puzzled to determine what to do. Holders are unable to discover any encouragement to reserve their stocks, while purchasers are afraid to buy more than they immediately require, as the probabilities are in favor of a further depreciation in prices. The opening of the Mississippi River is not regarded as of so much advantage to commercial interests, as to the National arms, in a military sense. Trade on the river, during the present war, it is argued must be attended with extraordinary hazard, and therefore can not become very extensive or prosperous, before the return of peace. It is true that the impoverished people of the valley, within the limits of the rebellious States, must need and doubtless procure supplies of food; but any demand, beyond this, is not looked for immediately. As a means of conveying produce to the seaboard for shipment thence, the Mississippi can not be relied upon, until hostilities shall have been brought to a close. The Canals and Railroads of the loyal North will consequently continue to the end of the war to enjoy a monopoly of the forwarding business. New-York will continue to receive the bulk of the produce coming eastward from the interior, and stocks in this market will be likely to keep in excess of the actual wants of the trade of the port, which will depend for its volume and prosperity, very largely on the premium which gold will command. If gold should continue to decline, merchants apprehend a sweeping derangement of business, temporary it is true, but, nevertheless, decidedly injurious. As it is, the fall of 25 @ 30 per cent. has had a most depressing influence on all commercial interests, and caused unusual irregularity

SANFORD & MALLORY'S PORTABLE FLAX AND HEMP DRESSER.

Date of Patents, Sept. 16, 1862, and April 28, 1863.

Over Fifty of these Machines have been in practical use during the past season, and so great is the demand for the coming Fall that we have adopted the following plan, viz.: That we will only make to order. Many have already sent in their orders for

Those who desire to use our Machine in dressing the crop of the present season, would do well to send their orders without delay, as all Machines are delivered according to the date of the order.

Made and Sold by
MALLORY & SANFORD,
HARLEM RAILROAD BUILDING,
Room No. 26, in White-st., near Centre.

Our terms are Cash on delivery of shipper's receipt or bill of lading, and persons ordering can send draft on New-York, or Treasury Notes, to some person here whom they know, or by Express, to be delivered to us on our delivery of bill of lading for shipment of Machine. Price at our Factory, at Paterson, New-Jersey, for
No. 1 Machine, (capable of dressing 2,500 lbs. of Flax Straw in ten hours,) \$355.
No. 2, \$255. No. 3, Hand Machine, \$155.

FIRST.—A machine capable of dressing 2,500 pounds of flax straw in ten hours, can be sold at the factory, ready for shipment, at \$355; and the second size capable of dressing 1,500 pounds of straw at \$255. A third size, capable of dressing from 600 to 800 pounds of straw per day, at \$155. The smallest size weighs about 300 pounds and can be run by hand.

SECOND.—The yield of flax fibre by the use of this machine, in proportion to the weight of flax straw dressed, EXCEEDS BY AT LEAST ONE-FOURTH that obtained by any other machine or process.

THIRD.—The fibre, dressed by this machine, is much more valuable than that dressed in any other way, on account of the greater yield over the hackle.

FOURTH.—This machine is so simple in its construction and operation, that the liability to derangement is very slight.

FIFTH.—This machine does not require in its use any peculiar skill. It can be operated by boys or girls, and does not involve any risk to the hands or arms of the operatives, while the ordinary machines require the use of skilled labor, and as experience has proved, are always attended with risk to the operatives.

SIXTH.—This machine can be driven by any of the horse powers in use, and as it can be operated by ordinary farm labor, it enables the farmer to dress and prepare for market, at little expense, the flax raised by himself, thus opening to him a new and profitable occupation.

SEVENTH.—This machine is small, the largest size occupying only about four feet square, and weighing not over 1,100 pounds.

As there is a demand for larger machines for hemp, the proprietors are building such, capable of dressing two and-a-half tons of hemp straw per day.

The amount of flax fibre produced in the United States in the year 1850 was 7,806,800 pounds. Had the straw from which this amount of fibre was taken, been dressed by the Sanford & Mallory Machine, the yield would have been not less than 10,409,073 pounds. The increased product or the flax saved, at present prices, would be worth \$650,542.

When it is remembered that in many of the Western States an immense quantity of flax is raised for the seed alone, the straw being destroyed or wasted as of no value, it will readily be seen that the introduction among farmers and manufacturers of a cheap and effective machine, capable of converting what would otherwise go to waste, into an arti-

cle of great value, can not fail to produce the most important results.

It is well known that flax can be successfully cultivated in all the Northern States. If in addition to the value of the seed—sufficient of itself to pay the entire cost of cultivation—the straw can be made a source of large profit, a wide field of successful industry will be opened.

That the statements here put forward as to the efficiency and value of the Sanford & Mallory Machine, and especially as to the great saving effected by it over any other machine or process known, are rather below than beyond the fact, will abundantly appear from the subjoined reports and letters from practical flax-workers and dealers. Nothing need be added to their direct and positive testimony.

Over fifty of these machines for flax and hemp have been in successful use during the past season, in different parts of the country, and the demand for them is now large—consequently, orders for them should be made early, as the coming crop of flax and hemp will soon be ready for dressing.

The demand for flax during the past year and-a-half has quite doubled its price, and it is now used for many purposes to which it was never before applied, and for which it is found to be superior to cotton and other materials before in use. Whatever, therefore, may be the future product of cotton, the demand for flax will not diminish, but, on the contrary, increase with its new and useful applications. It is now largely mixed with woolen goods of almost every description; is used for paper, wadding, batting, belting, druggets, delaines, calicoes, stockings, felt hats, and carpeting. Should the experiments for cottonizing flax, for which Congress has made a large appropriation, succeed, the already large demand for it would not only be enormously enhanced, but made practically unlimited.

Take a given quantity of Flax Straw, either over or under retted, and pass it once through this Machine and it will invariably have lost four-fifths of the shooove or woody part, without the least fibre of tow. The Machine requires two men, or boys, to tend it, and runs from eighteen to twenty hundred lbs. of straw in ten hours. There is no risk whatever to life or limb of the operator.

A dry or wet day makes no difference with this Machine, with reference to its result in the saving of Fibre.

The Machine can be seen in operation any day at room No. 26, Harlem R. R. Building, corner of White and Center Streets, New-York City, or at Mr. Harvy Wilcox's Flax Mill in Union Village, Washington County, N. Y.

This Machine with one-horse power will also run from four to six hundred lbs. of Hemp stalks per hour; leaving the fibre perfectly clean and straight, with not one ounce of tow to the ton.

Those desiring Machines this fall should order at once, as we shall supply according to the date of orders.

TESTIMONIALS.

LAKE, Washington Co., N. Y., Nov. 7th, 1862.

MESSRS. MALLORY & SANFORD:

GENTLEMEN.—On the 6th of Nov. I took two lots of very tender straw, as nearly alike as possible, each weighing 26½ lbs. One lot I had dressed at a neighboring flax mill (as good as the average of mills in this country), and the yield was 2 lbs. 13 oz., dressed flax, and 2½ lbs. of tow. I then had the other 26½ lbs. broken in your brake, and scutched in the usual way—the yield was 5 lbs. 5½ oz. dressed flax, and no tow of any amount. I can assure you I was much surprised at the result. To-day I have seen, at the mill of Mr. Harvy Wilcox, a very thorough experiment, testing the relative working of your machine and the old brake. 50 lbs. straw broken in your machine weighed after breaking 21½ lbs. The same quantity broken in the old brake weighed after breaking 38 lbs. A lot of 350 lbs. was then broken in your machine and scutched with the following results:
Time of breaking .1h. 36 min. Yield of coarse tow...10 lbs.
“ “ scutched 1h. 36 min. “ “ fine tow....2½ lbs.
Yield of dressed flax...79½ lbs.

A lot of same quality and weight was then broken in the old brake and scutched:
Time of breaking .1h. 25 min. Yield of coarse tow...26 lbs.
“ “ scutched 1h. 28 min. “ “ fine tow....6½ lbs.
Yield of dressed flax...64 lbs.

I have been engaged in the flax mill business nine years, and have experimented a great deal in flax dressing, and from what I have seen of your machine, I am confident that with skillful use it will yield, when tender straw is dressed, at least 10 lbs. of lint to 100 lbs. of straw, more than any other machine in use—and when straw of average quality is dressed, the saving will average at least 6 lbs. to the 100. And I think the coarse tow from your machine is worth full one cent per pound more than that from the old mode of dressing, while the flax dressed is invariably softer, longer and freer from shoove than any I have ever seen from the old process. Another feature of your Machine is, that it can be worked without the slightest risk to the operator. I have this day ordered from your Agent, Mr. Wilcox, two of your machines for my Mill.

Yours truly, ENOS DURHAM.

LAKE, May 11th, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN—I think that I promised you that I would write you and let you know how the brakes work after having the new gear put on, and now (after working them two months) I think I can safely say that they are perfect. They work perfectly easy, that jerking noise is entirely done away with; consequently there is little or no strain on the gear, and not liable to get out of order. In regard to the working of the brake I have seen nothing to alter my mind since last Fall, after running them six months; on the contrary, I have become confirmed in what I stated last Fall, have tried them in opposition to the old brake several times, and always with nearly the same results. I will give one or two specimens. I was at Wm. McMillen's mill last winter, and we were in conversation about your brake. We finally agreed on a test. Accordingly, he selected two bundles (nine and one-half pounds each), first quality of straw, and east lots, by turning his back, &c. The bundle that fell to him was dressed in his mill, and made two pounds, six ounces, of lint; the other I brought home and broke it with your brake, and dressed three pounds of lint. The tow we paid no attention to in either case. This morning I took a bundle of straw that weighed eight pounds, ran it through the brake, and it weighed three pounds, four ounces. I then dressed it, and got two pounds of flax and four ounces of tow, not very heavy coated. I think with good quality of straw, well-rotted and dry, it will take out nine-tenths of the shives. I do not want you to think that flax can not be wasted after your brake; on the contrary, I know that hands do waste a great deal of flax that might be saved by good management, but that is no fault of the machinery. I suppose you have forwarded a machine to Richardson in Iowa. I hope so.

Yours truly, ENOS DURHAM.

“ROUGHFORT, Ireland, April 9th, 1863.

“DEAR SIR,—I have to report to you on the merits of Mallory & Sanford's American brake, which has been at my scutched mill for the last three weeks. I have tried it on various kinds of straw, and find the results as follows: On very poor and hard straw I found a gain of one pound per hundred weight over the same broken by ordinary rollers; on medium quality of straw a gain of two pounds, four ounces per hundred weight, the yield by your brake being eighteen pounds, four ounces against sixteen pounds on same straw broken by ordinary method; on very tender straw, over-watered, the gain was three and a half pounds per hundred weight, the yield by your brake being fourteen and a half pounds against eleven pounds by ordinary method. I find the flax from your rollers easier scutched, and the yield softer to feel and quality improved over that rolled in the ordinary way.

Yours truly, JOHN WILLIAMSON.

“MR. ALEX. GUILD, Belfast.”

SPRINGFIELD, Clark County, Ohio, May 5th, 1863.

MESSRS. MALLORY & SANFORD:—

GENTLEMEN.—I have tried one of your brakes, and I have run through thirty-one hundred pounds in ten and one-fourth hours, which was well broken, and every way satisfactory. I am, gentlemen, yours respectfully,

E. MEEK.

BONE MANURE.

Order early. The supply is limited. We sell a pure article.
GRIFFING, BROTHER & CO.,
60 Courtland-st., New-York.

STRAWBERRY PLANTS By Mail.

Will be ready in August and September—Choice plants
for mailing—being stout and strong.

Triomphe de Gand, Great Austin or Shaker, and Wilson's
Seedling. The very best for family use and market.

For a remittance of \$1.30, 100 plants of either kind, or a
100 assortment will be sent to the Post Office address of those
ordering.

100 plants grown as I direct, will produce over 3 bushels of
fruit. Good Plants \$6 per 1000.

J. C. THOMPSON, Tompkinsville,
Staten Island, N. Y.

Strawberry Plants.

Triomphe de Gand, Wilson's Albany, Hooker, Fill-
more, Bartlett, Ward's Favorite, and forty other varieties in
large quantities, at low rates, at wholesale and retail. Cat-
alogues gratis.

FRANCIS BRILL,
Newark, New-Jersey.

FRUIT AND ORNAMENTAL TREES. RARE CHANCES OFFERED.

200,000 Choice Fruit Trees, Vines, etc., for
sale, of varied size to suit customers.

The subscriber calls attention to his unusually large stock
of well grown trees now on hand, and especially to the pre-
sent stock of the STANDARD FRUIT, APPLE, which is the
largest and finest ever offered at these Nurseries.

With twenty years of experience, by careful observation
and judicious selections, he believes he is able to judge and
furnish what will suit his customers, as well as the varied
soils and localities, in which trees may be wanted. There is
also special attention paid to local varieties, adapted to
Southern and Central Pennsylvania, many of which have
proven themselves more valuable, than sorts originating in
a climate differing so widely from these sections.

He is also preparing a list of ELUM PRIERS for those who
purchase direct from the proprietor, offering rare induc-
ments for neighbors to join together, and get trees consider-
ably under the regular retail prices.

This mode is adopted for those who may not have an op-
portunity to purchase from his regularly authorized agents,
and hold a mistrust towards the too numerous tree vendors
spread over the land.

The frequent use made of his name and establishment
by strangers, to effect sales where the reputation of the
nursery is known, compels him to warn all not to purchase
—as coming from these Nurseries—stock offered by PRE-
TENDERS, who do not hold an authority from the proprietor.

Local or stationed agents will be accepted, but neither
traveling nor stationary agency inquiries will receive notice,
unless the parties produce satisfactory reference as to their
honesty in dealing with customers and employer. Send for
Catalogues and priced List, which contain inducements not
before offered by him. ABUNDANT AND TRUSTWORTHY RE-
FERENCE WILL BE FURNISHED TO ALL WHO ARE STRANG-
ERS TO THE ESTABLISHMENT.

Address DAVID MILLER, JR.,
Cumberland Nurseries, Carlisle, Pa.

GRAPE VINES.

Our Stock of all the new and leading kinds is unsurpassed
anywhere. Our New Price List will be issued September 1st,
and sent to all applicants free of charge.

J. KNOX,
Box 155, Pittsburgh, Pa.

Aberdeen, and other Turnip Seed.

Buckwheat and Seed Grain of best varieties.
Garden and Agricultural Seed, fresh and pure.

Wholesale and Retail by

R. H. ALLEN & CO., 189 & 191 Water-st., New-York.

TOBACCO.

Just How to Grow it.

Every particular, from the selection of the Seed, and
preparation of the ground, to the Gathering, Curing, and
Marketing the Crop, is given in a work issued by the
Publisher of the *American Agriculturist*, and sent post-
paid for 25 cents. This work consists of a selection of
the best fourteen out of eighty-five Essays, prepared by
eighty-five different cultivators, residing in various parts
of the Northern and Middle States. In each of the Essays
contained in this work, the writer tells, in a plain, practi-
cal, straight-forward manner, just what to do, and how to
do it. Any item omitted by one is given by another, so
that the information is full and complete. Several en-
gravings illustrating the method of drying, packing, etc.
The work is worth its weight in silver to every one grow-
ing even a small plot of tobacco.

STRAWBERRIES!!

The Subscriber will send any of the following choice
Strawberry Plants, post paid, to any part of the United
States (where there is postal communication), east of the
Rocky Mountains, on receipt of price, and will also insure
their safe arrival at destination.

For price of plants in larger quantities, and description of
the above and many other varieties, see our new Straw-
berry Catalogue, which will be ready the first of August, sent
free to all applicants who inclose two one-cent stamps. Ad-
dress ANDREW S. FULLER, Brooklyn, N. Y.

Strawberry Plants by Mail.

FOR ONE DOLLAR,

We will send to any Post Office address in the United States
or Territories, safely packed and post-paid,

One Dozen Plants

of each of the following kinds. Triomphe de Gand,
Wilson's Albany, and Burr's New Pine (the
best early).

FOR THREE DOLLARS,

We will send in equal quantities (33 of each) 100 Plants
of the above kinds: or for

FIVE DOLLARS,

300 Plants (100 of each).

The above embrace the different seasons of ripening, and
are all favorites with us. For further particulars send for
our Strawberry Circular, which will be furnished free.

J. KNOX,

Box 155, Pittsburgh, Pa.

New and Splendid Strawberries.

The prize berries of Europe, Empress Eugenie, Margarine,
and Princess Frederick William, plants \$1 per dozen.

Russell's Great Prolific. One of the most promising of the
American seedlings, berries produced this season, 6½ inches
in circumference; it is more prolific than the Wilson, su-
perior in flavor, and a splendid market berry, \$1.50 per dozen,
or \$9 per hundred.

Lenning's White, Albion White, White Pine Apple, and
Deftford White. These are great acquisitions, berries very
large, fine flavored and very productive, at \$1 per dozen.

La Constante. We would call attention to this variety, as
one of the most promising sorts in cultivation, at 50c. per
dozen, \$1 per hundred.

Oscar, Victory, Wizard of the North, River's Eliza, Bonte
de St. Julien, Crimson Queen, Wonderful, Filbert Pine,
Prince Imperial, Duc de Brabant, Boyden's Mammoth, and
Duc de Malakoff, at 50 cents per dozen.

Triomphe de Gand, Great Austin, Jenny Lind, Bartlett,
Fulton, or Chilian, at \$1 per hundred, \$6 per thousand. Ber-
ries of the great Austin were produced this season, weighing
1½ ounces. We think the Austin better than the Wilson, and
more productive. Plants delivered in rotation as ordered.
All orders addressed to
WM. S. CARPENTIER,
329 Greenwich-st., New-York.

Green Prolific Strawberry.

Produced from "Kitley's Goliath" and "Hovey's Seedling,"
by Seth Boyden Esq., and is one of the parents of his famous
seedling "AGRICULTURIST" which astonished the natives at
the late exhibition in New-York. In many points equal to
this wonderful new variety. Decidedly one of the best in
cultivation. Strong Plants \$1 per dozen. For a descriptive
circular or plants, Address

Hay Presses, Rock and Stump Extractors, Cider Mills, and Wrought Iron Screws.

These are tried machines, and are offered to the public at reduced prices. Having recently improved and taken out patent on press for baling, I am confident of its capabilities to bale one ton of hay, per hour, and put it in less space than any other press in use.

Rock Lifters, that do the work at small expense, requiring only one man and a boy to do the work effectually.

There is but one way to make fine cider. The grater mill is the only one to be relied on. I have been making these mills for the past 25 years, and can refer to different persons who have used the same mill for the last ten years, without extra expense, grinding from 15 to 20, and as high as 30,000 bushels in a season. One of these mills will grind perfectly fine 100 bushels in 40 minutes. They can be attached to any power, are simple and cheap, and, with wrought screws, will make a barrel of cider from six bushels of apples.

Also on hand, one large iron power press of 500 tons pressure, in perfect order, suitable for compressing hay or cotton, or for paper mill use, for wet or dry pressure, or for bookbinder's use, having a moving table, 30 by 48 inches.

S. N. STEBBINS, Actuary.

ABRAM DUBOIS, M. D., Medical Examiner.

The NONPAREIL WASHING MACHINE

Is the only entirely reliable machine in use.

It has been before the public two years, and has not in any instance failed to give satisfaction.

It saves two-thirds the labor and time required in hand washing.

It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it.

It will not get out of order.

It is recommended by Mr. Judd, the proprietor of this

Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20.

Send for free Circular to

OAKLEY & KEATING, 73 South-st., New-York.

J. C. Taylor, Holmdel, N. J.,

BREEDER OF

WEBB SOUTH DOWN SHEEP,

Would announce to his old customers and others, that he is now ready to supply a very superior lot of yearling rams, and ram and ewe lambs, besides a few breeding ewes, at private sale; also 5 rams to rent. For particulars send for circular.

Buy the best. If you buy a poor plow, when worn out you may buy another very superior. Not so with breeding animals; like produces like. If you begin your flock right, your increase will be right. My flock has no superior in America or England.

The great Want supplied.

FAMILY WINE AND CIDER MILL,

WITH PRESS COMBINED.

(HUTCHINSON'S PATENT.)

Costs but \$18. Grinds 6 to 8 bushels APPLES, 10 to 12 bushels GRAPES or CURRANTS per hour.

The Machine, excepting the curb, is made wholly of iron, prepared so that it does not affect the juice. It is easily handled and worked by one man, and takes up no more room than a chair.

A large number have been sold, and WITHOUT EXCEPTION give perfect satisfaction.

The Mill and Press complete, with a pamphlet containing full directions to make wine and cider in the best manner, will be forwarded upon the receipt of the price, \$18, by

J. B. BROWN & CO.,

PEEKSKILL, N. Y.,

Manufacturers of the celebrated Peekskill Plows, Best Iron Beam Plows, Land Rollers, and other Agricultural Implements. Send for Illustrated Circular.

Mills forwarded from New-York, if desired.

As the demand is certain to be large, orders should be sent in as early as possible.

DUTCHER'S LIGHTNING

FLY-KILLER

Supplies a want felt by every good housekeeper. Every sheet will kill a quart were flies are thick. Remember that it is DUTCHER'S that does this, and refuse the base imitations that are offered. The real article is for sale by all respectable Druggists.

Amalgam Belts.

At prices within the reach of every Church, School, Cemetery, Factory, or Farm in the land. Their use throughout the United States and Canada for the past six years has proven them to combine most valuable qualities, among which are TONE, STRENGTH, SOBERNESS, and DURABILITY OF VIBRATION, unequalled by any other manufacture. Sizes from 50 to 5,000 lbs., costing two thirds less than other metal, or 15 cents per pound at which price we warrant them twelve months. Old bell metal taken in exchange, or bought for cash. Send for a Circular to the Manufacturer.

JOHN B. ROBINSON,

No. 190 William-street, New-York.

GREAT DIS-
COVERY!

USEFUL and VALUABLE
DISCOVERY!

HILTON'S

INSOLUBLE CEMENT!

Is of more general practical utility than any invention now before the public. It has been thoroughly tested during the last two years by practical men, and pronounced by all to

Be Superior to any

Adhesive Preparation known.

Hilton's Insoluble Cement

A new thing. Is a new thing, and the result of years of study; its combination is on

SCIENTIFIC PRINCIPLES,

And under no circumstances or change of temperature, will it become corrupt or emit any offensive smell.

Boot and Shoe Manufacturers, using Machines, will find it the best article known for Cementing the Channels, as it works without delay, is not affected by any change of temperature.

Jewelers will find it sufficiently adhesive for their use, as has been proved.

It is especially adapted to Leather, and we claim as an especial merit, that it sticks patches and Linings to Boots and Shoes sufficiently strong without stitching.

IT IS THE ONLY

LIQUID CEMENT

Extant, that is a sure thing for mending Furniture, Crockery, Toys, Bone, Ivory, and articles of Household use.

REMEMBER

Hilton's Insoluble Cement Is in liquid form and as easily applied as paste.

Hilton's Insoluble Cement

Is insoluble in water or oil.

Hilton's Insoluble Cement

Adheres oily substances.

Supplied in Family or Manufacturers' Packages from 2 ounces to 100 lbs.

LAST MONTH

OF THE SPECIAL

Barometer Premium.

Our contract with Mr. Wilder, for supplying the "Woodruff Barometer" at premium rates, expires Aug. 31, and every one who can, should secure this extraordinarily liberal premium the present month. For general use it is the best and cheapest mercurial barometer to be obtained, even at the regular prices, while our offer makes it cost next to nothing. A person sending in 20 names at \$1 each, would get the \$12 barometer cheaply, even if he actually gave away to his friends and neighbors twelve of the copies subscribed for. But this need not be necessary. A little effort will obtain the full 20 persons, who would find the dollar invested in the paper a very good outlay. (Every one of them will come in for a share in the distribution of the New Strawberry Plant, page 240, next year, by adding the 5 cents for postage and packing material.) It only needs some one to exhibit the paper to them, and show its value, to induce many to subscribe; the barometer is offered as payment for their time to those who take the trouble to thus show the paper.

Its Value.—A good barometer is not only an interesting instrument, but it is also a very useful one in every house. The interest on \$8 or \$12, is only 50 cents to \$1 a year, and there are many times when it will repay this cost. After a little experience in observing a barometer, one can judge with a good deal of certainty, upon the land as well as upon the sea, with regard to the prospective weather. A sudden large fall of the mercury indicates a short, violent storm. A slow, steady sinking of the mercury, continuing through a day or two, indicates the approach of a long storm, even though the skies may then be clear. On the contrary, no matter how threatening the skies may appear, if the mercury does not fall, we may confidently look for the absence of storms. Other general rules, and exceptions, accompany each barometer, on a printed card. The instrument aids materially in deciding when to cut grass, grain, etc., and when to gather or leave them exposed in the field; when to undertake this or that work; how to dress for a day's journey; and in most other cases where it is desirable to decide upon the probable weather just ahead. Mr. Woodruff's newly invented mercury cup, the improved mode of packing in double boxes for carriage, and the low price of a good, reliable instrument, place these barometers first. They are carefully and neatly made, and are even ornamental. The two instruments shown in the engraving, are about 3 feet in length, and cost \$8 and \$12, the main difference being in the casing, which is more ornamental in fig. 2 (\$12), and this is the preferable instrument. Both have thermometer and vernier.

Fig. 1.

Fig. 2.

The \$8 form (fig. 1) we present to any person sending us this month 14 subscribers at \$1 a year.

The \$12 form (fig. 2) we present to any person sending this month 20 subscribers, at \$1 a year.

N.B.—Subscriptions for the above premiums are to date Jan. 1st, or July 1st, 1863.—Back numbers supplied.

Paying the Strawberry Premium.

Special Notice to those entitled to Strawberry Plants.—During the last of August and early part of September, we shall send out the Strawberry Plants offered as premiums during the past few months. Those entitled to them will please notify us by letter which of the kinds offered below they may desire. After watching the results this year, we find nothing superior for general culture to the *Triomphe de Gand*. There are others which will perhaps prove superior, but the plants can not yet be obtained in sufficient quantity. We shall therefore send the *Triomphe de Gand* where the Bartlett or Austin is not preferred. Those who have the *Triomphe* already, may choose either the Bartlett or the Austin. We are much pleased with the *Bartlett*, which has borne freely, a large well formed berry. From a plot 1½ rods wide, and 5 rods long, set only last season, we this year commenced picking a family supply June 12th: on June 14th, gathered a measured bushel; and continued a daily picking, up to July 1st. All the berries we could spare were eagerly taken at our place by dealers, at 18 cents per quart, for the unstemmed fruit. We do not place it before the *Triomphe*, though superior in some respects. It will make a good one for an assortment.

The *Austin* has proved better than we anticipated. It is a large vigorous grower, very productive, and continues bearing over a long season. We began picking on June 13th, and had from the same plot a fair picking on July 4th. The fruit is very large, which in part makes up for the want of high color, as a market berry. It is, however, better adapted for a home fruit than for marketing at a distance, as it is not firm enough to bear so severe handling as some others. We have reports of extraordinary crops and enormous market profits. Take it all in all, the *Austin*, though not the first, takes a pretty high rank, and is worthy of a place in every home garden.

Where premium plants are due for more than one subscriber, a part of the plants may be chosen from either two of the above three varieties. The premium offer closed July 31st, though we shall not be particular as to a few days in the limits of time, as the distribution will not commence until the latter part of August, the time depending upon the weather, and the localities to which the plants are to be sent.

Back Volumes & Numbers For Sale.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$1.50 each.

PRICES WHEN SENT POST-PAY BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, 20, or 21, unbound.....\$1.24 each.
Volumes 16, 17, 18, 19, 20, or 21, bound.....\$2.00 each.

Binding.—Sets of numbers sent to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 21 inclusive, at 25 cents per cover. Covers can not go by mail.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the *AGRICULTURIST* are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 12 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is twelve cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

VOLUME XXII—No. 9.

NEW-YORK, SEPTEMBER, 1863.

NEW SERIES—No. 200.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

September might properly be placed first in farmer's Calendar. Although each month brings its labors, this witnesses the commencement in cultivation of the great crop of the world, wheat, which for ages has taken pre-eminence among cereals, and upon which more than any other depends the most important interests of society. No man could estimate the results of the entire failure of this grain for only a single year: it would incite greater revolutions than history has yet recorded. The farmer may with honest pride often revert to the fact that he moves the great balance wheel of society, and it should be his constant endeavor to labor with a zeal and an intelligence befitting his station. Success in his calling is not merely a matter of personal gain, it brings a benefit to society, and its influence is felt in every sphere, from the mechanic in the workshop, to the statesman in the National Council. The progress of agricultural science, though slow compared with achievements in other fields, has contributed very largely to the present position of America among the nations, and enabled her thus far to resist a revolution which would have torn many other existing commonwealths to fragments. While we have bread to eat and to sell, our strength is untouched, though temporary reverses attend our arms.

The sower should go forth cheerfully at this time. The past three years have yielded unprecedented plenty. Scourges of drouth, of insects, and other inflictions ruinous to the wheat crop, have been confined to limited areas, the great aggregate has filled to overflowing the store-houses of the world, and the pockets of the producers. He must be perversely blind who fails to see in this the hand of that Providence

that guides the affairs of nations. Without such abundance the aspects of our great inter-cine struggle might have been very different. Foreign nations have not cared to raise their arms against a power to which, from scarcity at home, they were compelled to look for bread. It may perhaps be too much to expect that another abundant harvest will fill our granaries and coffers. Yet, whether this be decreed, or it shall occur that the land shall withhold a large increase, there is every reason for sowing wheat largely, for improving every acre that can be well tilled. The prospects abroad are darkened with a gathering storm of war. Should it burst upon Europe, then what was experienced during the Crimean campaign will be felt again; the demand for our breadstuffs will absorb all the surplus we may raise. In view of this contingency, and also of the fact that there are rarely four successive years of plenty, we advise a large investment in this direction. It should not be forgotten that effort may often be more profitably directed to securing increased return from the number of acres usually cultivated, rather than by enlarging the area put under cultivation. The former course requires less capital, less labor, and at the same time prepares the land for better returns in future. One hundred dollars properly used in draining, or other needed improvements, may increase the yield from ten to twenty per cent for a term of years.

Work for the Farm, Household, etc.

There will be little leisure on the farm this month. In addition to sowing winter grain, in many sections the corn will be ready to be cut up by the ground, early potatoes to be dug and marketed, and early apples to be gathered and disposed of. At the West, the great sorghum crop will demand attention, and those who have cultivated tobacco will find ample employment in cutting and curing. Much labor and vexation will be saved by having all necessary buildings and implements in readiness for each crop. The markets should be closely watched at this season, to determine when to dispose of grain, wool, etc. Very favorable contracts for future delivery may often be secured during the present month. Taking one year with another, it is safe to accept a price which will give a good profit on capital and labor invested.

Barns, and Outbuildings, particularly those in which hay and grain are stored, should be frequently examined, to secure their contents from injury by storms, vermin, etc. A good coat of paint will pay more than the interest of its cost in the preservation of wood-work exposed to the weather, and in the improved appearance of buildings. Autumn is a good time to apply it. Keep all buildings well insured, and protect houses and barns with lightning rods.

Beans properly harvested will command a good price. Cure and save the haulm or straw and the unripe pods for feeding to sheep.

Buckwheat should be harvested before ripe enough to waste by shelling. Save the straw for litter; it is of little value for feeding. If there be a good mill in the vicinity it will usually pay to have the grain ground for market.

Butter made this month and next, if properly worked and packed, may be kept for use or for marketing any time before next Spring, when it will command better prices. A good milk-room, clean utensils, good salt, and sufficient working are the essentials. Much labor will be saved by the use of a good butter worker.

Cabbages.—Market those which are mature, and keep the late crop well hoed to promote rapid growth and early heading.

Cattle.—Keep them well fed, especially milch cows, and those intended for fall beef. Give them corn or millet from the soiling patch, roots and tops from the beet and turnip field, and extra leaves from the cabbages, etc. Commence stall feeding early. The same amount of grain will make from ten to twenty per cent more flesh, if fed out before cold weather requires a large part of it to be used in keeping up the animal heat. Salt at least once a week, and allow free access to water.

Cellars.—Thoroughly cleanse and prepare for the reception of roots, apples, etc. Make rat proof by cementing the floors. Where many vegetables are to be stored, it is desirable to have a cellar under the barn for them.

Cisterns.—Cleanse before the fall rains, and if good well or spring water be not obtainable introduce a filter. Clean rain-water, even unfiltered, is the most wholesome for all purposes, and after a short experience is agreeable to the taste.

Corn.—Mark the earliest and most productive stalks to be reserved for seed, and leave it to fully ripen. Cut the stalks by the ground as soon as the grain is glazed, cure the stalks for fodder, and store under cover to be husked when time allows. See article on page 269.

Draining.—Attention is called to this item month by month, because it is believed to be one of the most desirable and best paying improvements to be introduced on most farms. It will be beneficial, not only by reclaiming swamp lands, but it will render any compact soil more productive by taking out the surplus water, giving access to the air which will bring nourishment to the roots of plants, and making the soil lighter, so that the rootlets can more easily make their way through it in their search for food. Try it according to plans described from time to time in former volumes, upon a single acre, if no more, and note the results. Finish off all winter grain fields with deep draining furrows to carry off surplus surface water.

Eggs.—Pack in salt those laid now, for winter use, and for selling about the holidays, when they are in large demand at the best prices.

Fences and Gates.—Cut timber for new ones needed. Replace all unsound posts and stakes before the high winds of Fall and Winter have prostrated them. Char the bottom of gate posts before setting, or give them a good coating of gas tar.

Flax should be pulled as soon as the stalk is of a yellowish tinge, the leaves having mostly fallen, and the center seed boll become of a brown color. Read articles on pages 76, 110, (March and April.)

Grain.—Thresh as soon as practicable, and store in secure bins, or market if prices are satisfactory. Carefully cleanse from weed seeds etc. Some dealers re-screen much of the grain received, and make a good profit by the improvement in quality. If good seed has not already been secured, select from the best growth before threshing, or procure it from reliable parties, and keep secure from vermin.

Hogs.—Commence feeding early, with refuse grain, bran, and unsound corn, and finish off with old corn if there be any on hand. Early made pork costs less and usually commands the best price. Keep the pens clean and well supplied with muck, weeds or straw, to absorb manure.

Manure-making and money-making are almost synonymous on old farms. Provide an abundant supply of muck for use in the stables and yards the coming winter. Secure the weeds, wild grass etc., from waste places, for the same purpose.

Plow at once for winter grain, if it be not already completed. Deepen the soil by going an inch below the last plowing. This can be done with less risk for winter grain, than with spring crops.

Potatoes not wanted for immediate marketing are better left in the ground as late as can be safely done without danger from frost. When dug they should be hosed as soon as practicable, and not left exposed to the sun. A potato digger (see description of one in August *Agriculturist*) is well worth its cost to those who raise this crop on a large scale. After digging, plow under tops and weeds, unless the latter have ripened seed, in which case they should be gathered and burned.

Poultry that have had the range of grain fields, are in good condition for early fattening for market. Confine and feed them liberally, and allow plenty of water, with dust or ashes to wallow in. Promote the laying of hens that are shut up, by feeding with scraps of refuse meat.

Root Crops.—Keep the soil well stirred, and allow no weeds to interfere with their growth. If standing too thickly, thin, and feed the surplus to cattle.

Rye.—Sow after oats, or a second crop may be taken from the same ground, if the land is in good heart. Sow a little later than wheat. The white variety has proved excellent in this vicinity.

Sheep.—A small allowance of grain occasionally will bring them into good condition to winter well. Salt regularly and allow plenty of water. Examine to discover any signs of foot-rot, and if it appears, apply remedies promptly, and separate diseased sheep from the rest of the flock.

Soiling Crops.—Feed to stock as needed, or cure for winter fodder if pasture be abundant.

Sorghum.—Cut as soon as the seed is ripened, and press and boil immediately. Improved apparatus will pay in convenience, and in quality of the syrup. Experiment in making sugar with a small portion, by manufacturing before the seed has ripened. Remove the seed from all before grinding.

Timothy.—Sow with winter grain for meadow, or it may be sowed alone; in the latter case increase the quantity of seed. A top-dressing of fine manure, after covering the seed, will be beneficial.

Weeds.—Allow none to scatter their seed for next year's crop. Cut and burn—or add to the compost heap such as are not nearly ripe.

Wheat.—The earlier sowed has uniformly succeeded best in standing the exposure of Winter, and in escaping injury from the midge. Drilling, where practicable, is every way preferable to sowing broadcast. Wheat growers should notice the

International Wheat Exhibition to be held at Rochester, September 8th, 9th, and 10th. Full particulars were given last month, page 236.

Orchard and Nursery.

The prospects are that the crop of fruit will be at best a moderate one, and the greater care should be taken in picking and marketing, and in drying and preserving any not otherwise disposed of. Those who send fruit to city markets, ought to know that it is sold almost entirely by its appearance. A lot of apples of indifferent quality, carefully picked and packed, will sell for more than a greatly superior fruit which has been beaten from the trees, and comes to market bearing evidence of carelessness in its preparation. Where the fruit runs unevenly, it is better to assort it, and make two qualities; a higher price for the whole will be realized. Let the quality of the fruit be uniform throughout the barrels or baskets. Those who practice the deception of topping off their packages with a few selected specimens, soon establish a bad reputation, and they get a lower price in the market. Barrels are now mostly examined through.

It requires some judgement to know just when to pick the early fruits, as there is but a short period between maturity and decay. Peaches and Fall pears especially, must be picked while still hard and able to bear carriage without bruising. Pick carefully, and avoid bruising in handling.

Budding is still in season with peach and other late growing trees. Look to those huddled last month and loosen the handages, if the growth of the stock has rendered them too tight. Where the buds have failed, the stock may be rebudded, if the bark still peels. Use well matured huds.

Drying Apples.—Well dried apples and peaches are likely to be in demand next season. Commence with the Autumn fruit; pare carefully and remove all the core; dry as rapidly as possible in order to get a bright light colored, saleable article.

Hoeing will still be required in the nursery rows. In running the plow or cultivator between the rows be careful not to injure the trees or roots.

Insects.—Those which are forming their cocoons and preparing their winter lodgings should be removed. If saw-dust is seen around a tree, search for the borer and follow him to the end of his hole with a wire or slender piece of whalebone.

Labels will be needed to mark trees sent out this Fall. Prepare a stock of these and of stakes during the season of comparative leisure.

Lands intended for Fall planting may be cleared up and prepared now by manuring and plowing.

Pits of peaches and plums may be buried in a hole, or placed in boxes of earth, for planting next Spring. Save from the fruit of healthy trees only.

Preserve a good supply of peaches, pears, plums, etc., in bottles or cans. See our previous volumes.

Pruning, if not finished last month, may be done now upon young trees, to form good, low heads.

Seeds of ornamental trees and shrubs should be gathered as fast as they ripen, and rightly labeled.

Seed Beds will need thorough weeding and copious watering, if the weather be dry.

Kitchen Garden.

The unusually hot weather, with frequent and copious rains have, in this vicinity at least, made a great "growing time." The crops not only grow with unusual vigor, but the weeds are forwarded with a rapidity almost appalling. The garden should at all times be kept free of weeds, and where the plants get too large to hoe conveniently, hand pulling must be resorted to. Now that the products of the garden are rapidly perfecting and crowding on in such profusion, care should be taken that nothing goes to waste. The surplus must be taken care of, and what can not be used should be either stored, marketed, or otherwise disposed of. Noth-

ing should be left to decay, merely because there is an abundance. Every thing should be cleared up, and all refuse find its way to the hog pen, cattle yard, or compost heap.

Beans.—Pick the late string beans before they become tough, and salt or pickle as directed last month. Save the earliest Limas ripe for seed, and shell and dry the green ones for winter use.

Cabbages and Cauliflowers.—The late plantings will need frequent hoeings. Where it is desired to winter plants over in cold frames for planting in early spring, the seed may be sown this month.

Celery.—After the plants are 8 or 10 inches high, the earthing up should commence, and it will have to be repeated every ten days or two weeks according to the rapidity of the growth. It is an operation which should be carefully performed, a bungler by breaking the leaves and getting earth into the crowns of the plants, may thus spoil half the crop. Where the leaves spread much, it may be necessary to bring them together and tie them at the first earthing. If tied, it should be done with a slender piece of bass matting, or a string so weak that it will break away as the plant grows. The earthing up should be done when both plants and earth are quite dry.

Corn.—As soon as the early crops are gathered, cut up the stalks and cure them for the cattle or feed them out green. Save always the largest and finest for seed. Dry an abundance for winter use.

Cucumbers.—Select for seed as directed last month. If the weather is dry, water in order to prolong the fruiting season. Go over the vines every day and gather for pickles. Cucumbers that are ripe or nearly so, may be made into sweet pickles, according to note on page 247 (last month).

Endive.—Forward by hoeing and liquid manure. Tie up for blanching when the plants are dry.

Kale for wintering over may be sown this month.

Manures.—The supply for next year's use should now be accumulating. The compost heap should grow rapidly at this season.

Melons.—Pick as soon as ripe, which may be known by the stem readily parting from the melon by a well defined line, and coming off with a very gentle pull. Keep them from contact with the ground as directed in last month's Calendar. Secure seeds from the earliest and best flavored specimens.

Onions.—Pull as soon as the falling off the tops indicates that they are ripe. Seeds for sets may be planted early in the month.

Parsley sown early this month will form plants for next Spring. They may be kept over by means of a covering of straw or litter.

Pickles.—The garden now supplies an abundance of material for the pickles; cucumbers, tomatoes, peppers, beans, green melons, cauliflowers, nasturtiums, etc., should be gathered before toughening.

Seeds.—Much of the success of next year's garden will depend upon the careful and judicious saving of seeds this month. We have in former numbers spoken at length on this subject. Of biennials—like beet, parsnip, salsify, etc.—preserve the finest specimens for setting out to produce seed next Spring.

Spinach.—Make preparation for early greens next Spring, by sowing early this month. Thin out as soon as large enough, keeping the bed clear of weeds.

Squashes.—Clear off the vines after the crop of summer varieties is taken. The Marrow will soon be fit for use. The Hubbard may be used, and will be found good, even when quite green.

Tomatoes.—These are now in the greatest plenty. Bottle a full supply for winter use and make catsup.

Turnips should now be growing finely. Keep well hoed and thinned.

Weeds.—See that no seeds of these are saved for another crop. One plant pulled green, or burned if ripe, may save the labor of destroying thousands of weeds hereafter.

Winter Cherries.—Gather as they ripen and pre-

serve, or pack in cotton with the hulls on for winter. These are not as well appreciated as they should be. They are easily cultivated, and make a "sauce" but little inferior to strawberries.

Fruit Garden.

Here fruit is to be gathered, weeds to be exterminated, and preparation made for new beds.

Blackberries.—As soon as the fruit is off, the old canes are to be cut out. Remove the superfluous new shoots, leaving only one or two to each root for next year's fruiting.

Grapes.—The early varieties will be ripening this month. Pick for market with the greatest care, and handle by the stems only. Shallow boxes or crates are better than baskets for sending to market. See great Grape Exhibition announced elsewhere.

Raspberries.—Follow the directions given for Blackberries above, and also last month's Calendar.

Strawberries.—New beds may be made this month. Read article on page 241 August *Agriculturist*. Cut the runners from those cultivated in hills, remove weeds, and keep the soil loose.

Flower Garden and Lawn.

The borders should be bright with the gorgeous colors of the Autumn blooming flowers. These have not the tender beauty and delicate fragrance of our Spring favorites, but they come with a richness of bloom that accords with the season of ripeness and maturity. New grounds may now be laid out and prepared for Fall planting. Draining can be done and walks laid out at this season.

Bulbs.—The latter part of this month is the best time to set out bulbs for spring blooming. See article on page 275, for general directions.

Bedding Plants.—Those which it is desirable to preserve, such as Fuchsias, Lantanas, Geraniums, etc., may be taken up and potted preparatory to putting into a cool part of the green-house or the cellar, to remain during Winter.

Chrysanthemums need to be carefully staked. Cut out all weak shoots and a finer bloom will be the result. Pot for house blooming.

Cuttings.—Put out a good stock of Petunias, Verbenas, and other bedding plants for winter keeping.

Dahlias.—These are now in full bloom, and will require constant care to keep them from being injured by the winds. If any strong limbs are in danger of breaking, put down extra stakes and tie them. Cut off the flowers as soon as they have passed their prime, marking the choice hills.

Evergreens.—These may be planted this month, though with more risk than in Spring. See precautions in August *Agriculturist*, under Orchard.

Flower Pots.—Construct or repair and have ready for the reception of plants. Where there is no green-house, a great many tender plants may be safely carried through the winter in a cold frame.

Gravel Walks.—These are still liable to the intrusion of weeds, and need to be raked and rolled.

Lawns will still need an occasional mowing, and thin places may have a liberal sprinkling of seed. See article on Lawns on page 274.

Seeds.—Care should be observed in saving these from only the choicest flowers. Do not trust to memory, but label as soon as gathered. Hardy annuals, like Phlox, Larkspur, Clarkia, etc., may be sown now. With a little litter thrown over them, they survive the Winter and give an early bloom.

Verbenas and Petunias.—Layers and cuttings may still be made, and those already rooted may be potted off, to flower during the Winter season.

Weeds.—There must be no abatement of vigilance with these until the frost stops their growth.

Green and Hot-Houses.

If it has not been already done, no time should be lost in putting the houses in a perfect state of readiness to receive the plants. Painting, glazing, fumigating, and cleansing generally, should be done at once. The flues and hot water apparatus should

be tested, and all necessary repairs made before the plants are brought in. Many of the tender things will require to be housed this month, and the paint should be hardened, and the dust and muss all over beforehand. Before the pots are brought in, they should be cleansed from dirt and moss, and the plants cut back into shape. All plants ought to be housed before the cool nights check their growth.

Air should be given freely every day, and the plants be gradually accustomed to the change from the open air to the confinement of the house.

Bulbs may be potted and kept in a cool place to be brought forward into bloom later in the season.

Camellias need repotting. Give frequent waterings while they are making their new growth.

Potting.—All the materials necessary for the Winter's potting, should be accumulated beforehand—pots, stakes, tags, leaf mold, loam and sand, all under cover and ready for immediate use. Many of the plants have become pot-bound during the Summer, and will need shifting. Those which were set in the borders, will probably need to have both root and branches cut back when potted. Give them shade and water after the operation.

Apiary in September.

Prepared by M. Quinby—By Request.

Bees having no poor neighbors around them, will not be apt to get into the despicable habit of robbing. It is not necessary that a hive should be nearly destitute of stores to make it poor; it may contain all the honey needed for two or three families, but if without bees to defend it, it is not rich. A rich hive contains both bees and honey in proper quantity. Bees have no better faculty than men to resist temptation. As long as they can attain all they want from flowers, they are content; but flowers fail now, and poor hives must suffer from the rich. The bee-keeper who is determined to keep about him a healthy tone of morals, will remove as far as practicable, all temptations to evil. Remove the poor hives at once. Examine carefully to determine which they are.... Do not put out any refuse honey. If you have such to feed, put it in a box and give it to some needy colony where others can not get it. New swarms strong enough to defend themselves, and yet not suitable for Winter, may stand until next month for the brood to hatch, before being taken. Old stocks containing foul brood, should be looked to now. There is great risk in letting them stand, because if robbed by colonies to be wintered, the seeds of disease are taken there for another year. Much mischief often results from neglecting this. The bees of such may be given to a queenless stock, if needed, but should not be introduced until they stand long enough after being driven out, to consume all the honey taken with them from the diseased hive. Some of the combs will be filled with the brood and honey mixed together, these should be cut out and buried entirely away from the bees. The healthy bees should not get a particle, unless sealed and skimmed. The top and side combs are usually clean, and may be strained out for use.... The Italians so far, have proved almost exempt from this disease. Will not any one, having the Italians, in districts where it exists, watch this point, and report.... All honey in the surplus boxes, not sealed, is now taken below. If you would secure it, take it as soon as the flowers fail. To keep it from dripping out of the cells, turn the boxes right side up, as soon as the bees are out.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed upon our tables since our last report:

FRUITS—Currants: Versailles, Cherry, Red Grape, Short-Bunched Red, Prince Albert, White Grape, and Champagne, shown by E. Williams, Mont Clair, N. J. **Red Provence,** Red Angers, La Hative, Versailles, Cherry, Victoria, Glorie de Sablons, Champagne, White Grape, Golden Cherry Plum; A. S. Fuller, Brooklyn Nurseries, N. Y. **Raspberries:** Improved Black Cap, Morrisania, N. Y. **Raspberries:** Improved Black Cap, Orange, Hudson River Antwerp; E. Williams, Mont Clair, N. J. **Catawissa;** W. S. Carpenter, Rye, N. Y. **Blackberries:** New-Rochelle, new variety of pink color, also new black kind, from France; Wm. F. Heins, Morrisania, N. Y. **Dorchester,** New-Rochelle, and a new American Seedling; E. Williams, Mont Clair, N. J.

.... **Gooseberries:** Lincolnshire, large; Jas. Hunt, Flat-bush, N. J. **American Seedling;** E. Williams, Mont Clair, N. J. **Apples:** Early Harvest; Alexander McDonald, Mt. Vernon, N. Y. **Curious double apple;** Jas. Brush, Brooklyn, N. Y. **Pears:** Osborn and Beurre Giffard; Wm. S. Carpenter, Rye, N. Y. **Figs** grown out-doors, very fine; Thomas Caruly, Washington Heights, N. Y. **Mulberries:** S. Tuttle, New-Haven, Conn. **Lenon,** very fine, one of 40 on same tree; Mrs. S. Craft, Glen Cove, N. Y.

FLOWERS, ETC.: Collection of Seedling Double Carnations, and Gladioluses, very fine; A. P. Cummings, Westchester Co., N. Y. **Chinese Trumpet Lily;** Alex. Marshall, Paterson, N. J. **Plant of Lavender;** Anton Strahlm, Pearl-st., New-York. **Bloom of Abranthus roseus;** Wm. Allston, Brooklyn, N. Y. **Dahlias:** R. Cunningham, Brooklyn, N. Y. **Cut Roses and Dahlias;** C. S. Pell, New-York Asylum. **Larkspurs, Carnations, Gladioluses, and splendid Collection of seedling Phloxes;** Wm. F. Heins, Morrisania, N. Y. **Blooms of Magnolia Soulangiana;** W. S. Carpenter, Rye, N. Y. **Double Dahlia;** Mr. Jacobs, Bergen, N. J. **Double Balsams;** A. Edwards, Shrewsbury, N. J. **Pigmy Marigolds;** H. T. Haviland, Brooklyn, N. Y. **Double Zinnia,** Dr. Peyton, New-York City. **Cut Flowers;** O. Judd, Flushing, N. Y. **Splendid Collection of Gladioluses,** 54 varieties; Andrew Bridgman, 878 Broadway, New-York.

VEGETABLES, ETC.: New species of Cucumber, white, and curious Tree Tomato; G. M. Usher, Port Richmond, N. Y. **Long Blood Beet and Early Turnip;** J. W. Perkins, Central Park Hospital, New-York City. **Cucumbers;** Barney Williams, Bath, N. Y. **One bunch Tomatoes,** weighing 9½ lbs., Apple and Fig Tomatoes, and enormous growth of Marlynea; Wm. F. Heins, Morrisania, N. Y. **Mandrake;** Israel Thorneil, Metuchen, N. J. **Red and White Wheat,** grown near St. Louis, Mo.

The Great Strawberry.

IMPORTANT EXPLANATIONS.

A number of persons appear not to have read carefully through what was said last month about distributing the wonderful New Strawberry. At least, so we judge from the tenor of many letters received. Owing to the absence of the Publisher, perhaps his intentions were not so fully explained as they might have been. To save writing letters, and to make the matter understood, we explain:

1.—As the New Strawberry (now called the "*Agriculturist Strawberry*," appeared to far excel both in size and intrinsic value anything ever before produced, it was decided to purchase all the plants, to multiply them, and to distribute them free among the subscribers to the *Agriculturist* for the year 1864 (Volume 23).

2.—There were but few plants in existence; we bought all but one which is in the hands of an amateur friend, and we are cultivating and multiplying them with the greatest care. We can not spare one this year for love or money. A hundred dollars for one plant have been offered by some cultivators who would like to get up a stock for sale, as they would bring a high price. We intend to keep them out of market, and distribute them free. Each plant will, perhaps, on the average, produce, 200 others for distribution next year. The Green-House will be brought into requisition as soon as the out-door multiplication ceases. So, then, the many who earnestly solicit "just one plant now," will see why we can not grant the favor and excuse us from writing them in reply.

3.—As some plan of distribution is necessary, we adopt the following: The plants will be sent to all paying subscribers for 1864 (including exchanges), if we can produce enough, and if there be not enough, then as far as they go, beginning in order with the first who pay in their subscriptions for 1864. (Exception.—Some have sent in their applications, saying they intended to subscribe. As the matter was not definitely understood last month, we have entered these names in order, on a separate list, and when the subscriptions come in, we will check off the names for the plants, if the subscribers will refer us to their application, giving about the date. Those applying whose subscriptions already extend into 1864, are entered for the plants.) HEREAFTER, to avoid trouble and mistakes, and to save much extra labor, we must ask that the application for plants come along with the subscription for 1864. We do not desire to hurry up renewals, though every name now booked up for next year, by so much diminishes the severe labors of December and January, when the great bulk of subscriptions are generally received. We hope to have at least one plant for every subscriber, but can not promise them positively, and therefore adopt the rule of "first come, first served."

4.—No difference is made between single subscribers, club subscribers, or those coming on premium lists, or from Agricultural Societies. The plants are designed for all regular (paid up) subscribers alike. Voluntary agents or dealers can have the plants for their customers, on the same terms as others, that is, when we receive the subscription price for 1864. We can not supply plants to those who buy only by the single number, as any copy taken thus may be the last one.

ABOUT THE FIVE CENTS.—The purchase, cultivation, and distribution of the plants will cost \$3000,

or more, besides postage and packing material. The smallest parcel will require at least three cents worth of oil cloth, and two cents for postage. This five cents is a trifle for each, while if we paid it, it would amount to several thousands of dollars. Our paper is too low priced to afford profit for so much extra expense. It is a matter of necessity, therefore, to ask each one desiring the plants to enclose five cents for packing material and postage.

If this New Strawberry turns out as well as it promises, and as well as every one who has seen it believes it will, it will be a magnificent acquisition to the country, and the subscribers receiving the plants will get the first benefit at very trifling cost or risk, while the whole country will soon be supplied, at a cheap rate. Had we not secured them, they would have been offered at a dollar or more each, and thousands of persons would have paid \$5 to \$10 a dozen before they became generally disseminated. Indeed we could to-day sell our plants for \$3000 cash.

Great American Grape Exhibition.

THE NEW-YORK FRUIT GROWERS at their meeting, August 13, decided to hold a Public Exhibition devoted entirely to *Grapes*, at the *Agriculturist* Rooms, 41 Park-Row, on **October 1st, 2nd, and 3rd.**

The following gentlemen were appointed a Committee of Arrangements: Peter B. Mead, Esq., Ed. Horticulturist; R. G. Pardee, Esq.; Dr. I. M. Ward; Wm. S. Carpenter, Esq.; A. S. Fuller, Esq.; and Dr. C. W. Grant. The Committee report as follows:

PRIZES.

NATIVE GRAPE.

- A.—Best Native Seedling Grape that has never taken a prize—of superior quality, and ripening in open ground not later than Sept. 20th.—Satisfactory proof of time of ripening to be furnished. \$10
- B.—For the Best Collection of Native Grapes, (amount and quality both considered,) not less than 12 kinds, 5 bunches of each. 10
- C.—For Second do do do 5
- D.—For Best Six Varieties, 5 bunches of each 4
- E.—Second do do do 3
- F.—For Best Four Varieties, 5 bunches of each. 2
- G.—For Second do do do 2
- H.—For the Best 5 bunches of Native Grapes of any kind, quality to rule. 2
- I.—For the Best 5 bunches of Delaware. 2
- J.—For the Best 5 bunches of Diana. 2
- K.—For the Best 5 bunches of Catawba. 2
- L.—For the Best 5 bunches of Isabella. 2
- M.—For the Best 5 bunches of Concord. 2
- N.—For the Best 5 bunches of Hartford Prolific. 2
- O.—For the Best 5 bunches of Herbmout. 2
- P.—For the Best 5 bunches of Elsingburgh. 2
- Q.—For the Best 5 bunches of Creveling. 2
- R.—For the Best 5 bunches of Union Village. 2
- S.—For the Best 5 bunches of Anna. 2
- T.—For the Best 5 bunches of Allen's Hybrid. 2
- U.—For the Heaviest bunch of any kind. 2

FOREIGN GRAPE.

- V.—Best Six varieties, 2 bunches each 5
- W.—Second do do 3
- X.—Best 2 bunches Black Hamburg. 1
- Y.—Best 2 bunches Muscat of Alexandria. 1
- Z.—Best 2 bunches Grizzly Frontignan. 1
- aa.—Best 2 bunches of any other kind. 1
- bb.—Other Special Prizes to be awarded by the Judges, for extra specimens not included anywhere above.

REGULATIONS.—1. The Judges will be requested to select specimens by actual taste, and to make all other points subordinate to that of quality, except in Prize U. They will disqualify all lots not meeting the terms of the schedule, including the number of bunches called for (except in prizes B and C.). All bunches above the required number must be laid aside until after the judges have given in their decision, when the exhibitors may add to their specimens at their pleasure.

2.—Exhibitors should give at least 3 days' notice of the space required, that room may be provided for them.

3.—All specimens to be on the tables by 11 o'clock A.M. Thursday, Oct. 1st. The Judges will have exclusive use of the rooms from 12 to 2 o'clock, after which the public will be admitted. After the awards, the Prize specimens will be labeled. Exhibitors may then put on their specimens their cards, place of business, etc. No fruit will be removed before 4½ o'clock P. M., Saturday, without special permit. The fruit of course will belong to the several exhibitors, at the close of the Exhibition.

On behalf of the Committee,

PETER B. MEAD, *Chairman.*

The above report was presented and adopted at the Fruit Growers' Meeting, Aug. 20, and appointment made of the following excellent committee of

JUDGES FOR THE GRAPE EXHIBITION.

HON. MARSHALL P. WILDER, *Dorchester, Mass.*
CHARLES DOWNING, Esq., *Newburgh, N. Y.*
JOHN E. MOTTIER, Esq., *Cincinnati, Ohio.*
A. W. HARRISON, Esq., *Philadelphia, Pa.*
Dr. J. B. CHAPIN, *Providence, R. I.*
T. T. LYON, Esq., *Plymouth, Mich.*
JOHN DAILEDONZE, Esq., *Flatbush, L. I.*
ISAAC BUCHANAN, Esq., *New-York City.*

Containing a great variety of items, including many good hints and suggestions which we give here in small type and condensed form, for want of space elsewhere.

Mailing Strawberry Plants due for Premiums.—These will be mailed soon after Sept. 1st. (The dry season prevented an earlier development of well rooted plants.) The *Triomphe de Gand* will be sent where the Bartlett or Austin have not been specially called for. As soon as they arrive, remove the covering, and bury the roots in moist earth, if not ready to plant at once. (See directions for culture in August *Agriculturist*, page 241). Let the soil be made mellow and deep, and contain plenty of black earth, or woods mold, or well rotted manure. Spread out the roots well; set so that on settling the crowns will be fully as high as the general surface with no dirt on the central leaves; water only as needed—not drowning them; put a little rotten manure around each plant, and water through this, which will work in some of it, and stimulate the plants to active growth. All this, if the best results are desired. Rich manure in Spring promotes rapid growth of plants at the expense of fruit. With care in planting and a good autumn season, quite a number of new plants may grow, ready for spring planting. If set well apart, and well treated, 10 plants set now ought to produce at least 500 by next August. We could easily make 1000.

The Fruit Growers' Meetings, which were partially interrupted by hot weather, by the mob excitement, etc., are again in active operation. It will pay to drop in at 41 Park Row, on Thursdays, at 1 P. M.

The Great Grape Exhibition announced in another column is worthy of attention. The show will doubtless be one of the best, if not the best ever seen in this country.

The Premium Grape Vines, Due, can not be mailed until the new wood ripens, several weeks hence. The time of sending will be announced.

Fine Show of Gladiolus.—Our exhibition tables are blooming like a garden, with a splendid collection of over 50 varieties of gladiolus from the grounds of A. Bridgeman, 875 Broadway. The colors range from pure white with purple markings, to deep scarlet. We have never seen a finer collection. The gladiolus is one of the most desirable ornaments of the garden; it blooms in midsummer, and continues to flower until late in the season. Most of the sorts are hardy, and the bulbs only need taking up to divide them.

A Supplement to Ure's Dictionary of Arts, Manufactures, and Mines.—New-York: D. Appleton & Co. Ure's Dictionary has long been a useful hand-book of reference to those having an interest in the subjects on which it treats. This supplement, edited by Robert Hunt, and comprising contributions from numerous well-known authors, is a valuable work. It gives an exposition of all the latest improvements in manufactures, and embodies a mass of information not to be found elsewhere. Messrs. Appleton & Co. are issuing several scientific works of a high order; they will receive the thanks of all lovers of good books.

Flowers for the Parlor and Garden, by Edward Sprague Rand jr., Boston, J. E. Tilton & Co. We have a natural antipathy to works in which the chapters are headed by a poetical quotation. We confess that we opened this book with a prejudice against it, but we have given it a careful perusal, and must say that it contains much useful information for the amateur cultivator. There are some errors in botanical nomenclature which are evidently oversights, and should be corrected in another edition. The work is beautifully executed, and is not dear at the price, \$2.50. We shall place it on our book list.

A Good "Notice."—We do not feel at liberty to occupy much space in printing the good things said concerning this Journal by other Journals, and by our readers in their letters. It may gratify the members of the great *Agriculturist* family, however, to state that thousands of kind and appreciating notices appear every year, in which the merits of this paper are spoken of in the highest terms. We are gratified by such expressions of appreciation, and are thus stimulated to greater exertions. We give one example from a recent number of the "*Medical and Surgical Reporter*," of Philadelphia, one of the best and most widely circulated weekly Med-

ical Journals in the world. Praise from such a source is truly worth having. The Reporter says:—"The *American Agriculturist*, published by ORANGE JUDD in New-York, is one of the best and most practical, as it is the "cheapest paper issued for the use of agriculturists. As many of our readers are, to a greater or less extent, agriculturists and horticulturists, we unhesitatingly recommend it to their notice. The *Agriculturist* is an uncommonly promising opponent of quackery in medicine, refusing to advertise for quacks at any price, and devoting much space to a practical exposure of their tricks. Each number contains something to amuse and instruct children as well as grown persons. The price is but one dollar a year, and each number is worth the money."

Fine Wool and Sheep Husbandry.

—A work bearing this title is just being issued by C. M. Saxton. It consists of an essay by Henry S. Randall, L. L. D., read before the New-York State Agricultural Society, Feb. 12, 1862, and contains sundry matters of interest to breeders of fine sheep. A large part of the work is occupied with the history of different importations into this country, and a comparison of the values of the several breeds of fine-wooled sheep. It also contains practical suggestions upon the breeding and management of sheep. We can send it post-paid upon receipt of the price, 75c.

New Use for the Wringer.—Geo. M. Usher, of Port Richmond, informs us that he finds the Clothes-Wringer of great use in squeezing the juice from currants. The fruit is put into a bag, without being stemmed, and the whole is passed between the rollers of the Wringer. Mr. U. says he can thus make a barrel of juice as soon as he could a gallon in the ordinary manner.

The Barometer and the Church Bell.

—Rev. B. F. Sharp, Geauga Co., O., last year secured a premium barometer by obtaining subscribers to the *Agriculturist*. He writes that it has proved entirely satisfactory to himself, and of no little benefit to his neighbors. During haying and harvest, when the instrument indicated approaching rain, he notified his parishioners by ringing the church bell. One of them informed him that he saved five loads of hay in one day, by attending to the warning thus given.

Poisoning by Mercury Vine.—"W. T. P.," Monmouth Co., N. J. If you will tell us what the "Mercury Vine" is, we may publish the recipe. Is it the Poison Ivy described on another page?

Corn Blossoms.—City Subscriber, N. Y. If you read the Boys and Girls' Garden for this month you will better understand our answer. The Tassel is a collection of staminate flowers; the Ear a great number of pistillate ones. The silk of the corn is the long pistils, each thread of which comes from a pistillate flower that, after receiving the pollen from the tassel above, becomes a kernel. The staminate flower is much like the oat flower figured in the lesson. The structure of the pistillate flower is a little difficult to explain to one who is not a botanical student. You must take our word that it is so.

Fruit Notes.—Isaac Hicks, an experienced fruit grower in Queens Co., L. I., sends us the following:

PRIMATE APPLE.—We have had this superior summer apple several years under the name of *Tart Bough*. It was introduced from the vicinity of Syracuse, is nearly as early as the Harvest, and a much better grower, and more productive and valuable. It is very tender and juicy, and ripens gradually on the trees, so that it is in use three or four weeks.

CHERRIES.—Gov. Wood is the finest cherry we have yet tested, of about 30 varieties. All our Early Richmond and others of that class are nearly destroyed by the knot. Cutting off the knots as soon as they appear will prevent the spread of the disease if all your neighbors will pursue that plan, but if not, the labor is in vain.

DORCHESTER BLACKBERRY.—Of little value compared with New-Rochelle—thrown away after two years' trial.

STRAWBERRIES.—It is time the attention of the public was turned more to the flavor of this fruit, for any person that visited the Show at the *Agriculturist* office must be convinced that we have produced berries large enough. A strawberry that is rich and sweet enough without sugar, and of course productive too, is what we want now. Friend Fuller has succeeded in producing a seedling that approaches the mark, and Wm. E. Burgess, has a new variety that is very near what I desire, and can safely recommend, after visiting the grounds of the gentlemen above named in strawberry time, these seedlings to those who prefer flavor to size alone. We thought they were the best of the many varieties we tasted, and thrifty and productive also.

GRAPE.—Pick off one half of your Hartford Prolific grapes, and they will be more than twice the better for it.

Mummy Wheat.—J. M. Shaw, of Lee Co., Ill., sends us a sample of wheat "said to have originated from that found with an Egyptian mummy some years ago," and asks what are its qualities. We have not the least confidence in the mummy story; it is one of the popular errors. The wheat sent, has a remarkably long and black beard. The head is short, but well filled. The grain is plump, but from inspection merely, we should not think it would make the best quality of flour. We have no knowledge of this variety, and should be very glad if Mr. S. can answer his questions from experience.

Chewing Tobacco.—We have had numerous inquiries as to the method of converting leaf tobacco into the manufactured or chewing tobacco, but can give no positive information on the subject. We only know, in a general way, that the tobacco is sprinkled with water sweetened with molasses or liquorice, and sometimes flavored with vanilla or some other aromatic. It is then rolled into balls and submitted to strong pressure, which forms it into cakes. The manufacturing is usually done on a large scale by those who buy the leaf, and make a business of it, the same as with cotton or wool.

What is Muck?—City Farmer, Buffalo, N. Y., says that we often mention the use of muck, and he confesses that he does not know what it is. If we were to call it swamp mud, perhaps he would know it. It is the deposit found in low swampy places where partly decomposed vegetable matter has been accumulating for ages. When dug out and exposed to the air, it partially dries and becomes a valuable absorbent of gases from manure, and is of itself an excellent manure from the large amount of vegetable matter it contains. There are few farms of any extent that have not deposits of muck or black earth at some point.

Sex of Eggs.—Charles H. Grower, of Long Island, says in reference to Mr. Genin's plan for determining the sex of eggs (given in the June *Agriculturist*), that wishing to have a number of cocks, he put a dozen eggs with rough ends under a hen, and two males and seven females were hatched out. Seeing it stated in Bennett's American Poultryer, that if the air bubble is in the centre of the end of the egg, a male bird would be produced, and if slightly at one side the egg would give a female, he tried 15 eggs selected as male, and the result was 7 males and 6 females.

Canada Thistle.—The Legislature of Pennsylvania in 1862 passed a law requiring owners or occupiers of lands on which Canada Thistle may be growing, to cut the same, so as to prevent it from going to seed, and the seed from ripening, under a penalty of \$15; and providing further, that if any such person shall neglect or refuse, after receiving five days' notice in writing, to cut and destroy such thistles, it shall be lawful for any person aggrieved, or believing themselves about to be injured thereby, to enter on such lands, and cut and destroy such thistles, and recover compensation therefor from such owner or occupier, at the rate of \$2 per day. A similar law was recently enacted in Michigan.

How Can I Destroy Horse-radish? asks F. M. Abury, Washington Co., Pa. We know of no other way than to actually dig it out. The ground must be spaded up and forked over at least two spades deep, and all the roots, even to the smallest particles picked out. It is a difficult task, but we have successfully accomplished it. Horse-radish should never be planted except where it can remain permanently.

Yellow Daisy.—M. R. Campbell, Columbiana Co., Ohio. We do not know what plant you refer to. Send us a specimen.

Kerosene on Plum Trees.—In the February number of the *Agriculturist* we published a note from M. A. P. Richardson, of Norfolk Co., Mass., to the effect that he had kept his trees free from curculio by the use of kerosene oil applied to a band of cotton surrounding the tree. We have had several letters from those who have tried it and killed their trees. We published this as we do other items which come to us apparently in good faith. We cannot try every recipe and experiment ourselves. We deeply regret that any trees have been destroyed by what would seem to be a safe application. We shall be glad to hear if Mr. Richardson continues the practice with safety, and if he can account for its success with him and its disastrous effects in other places.

Tree Peddlers.—W. W. Beck, writing from Montgomery Co., Ind., says all we have written of itinerant tree vendors is true. His neighbors have patron-

ized them, and generally lost half their trees—in some cases all of them. He ordered and paid for one standard pear and two apple trees. The pear proved a poor, forked dwarf, and the apples were not the variety ordered.

Shade Trees Free from Span Worms.—I. C. Brooklyn, L. I. Few trees, save the Ailanthus, are exempt from worms, in badly infested localities like yours. On account of this freedom, and its rapid growth, even in poor soil, we often advise planting the Ailanthus along the streets of cities. The Sweet Gum (Liquidambar) is a pretty tree, on rich soil, and tolerably free from worms. The Linden is one of the worst preyed upon, and the Elm and Maple come next.

Gang Plows.—A. D. Henry, Lycoming Co., Pa. Gang plows of various patterns are in use in different sections of the country, particularly at the West, but they are not as common as we think they might be with advantage. Perhaps some modification in the present construction is needed to make them satisfactory. We are not prepared to name the best. Hildreth's is a good one, though not having seen it advertised recently, we cannot say where it is manufactured or for sale.

Hubbard Squash.—John A. Allen, St. Louis Co., Mo., has had much trouble from the destruction of the flowers of his vines by the squash-bug. The only remedy we can suggest is to begin early in the season, and look over the vines every day and destroy the insects. By killing those which come early, before they lay their eggs, much may be gained. The eggs are deposited on the under side of the leaves: these and the young insects, and in fact those in every stage of growth must be crushed. We know of no preparation or application which will keep them off.

Treatment of Raspberries.—T. W. Kingsbury, Pike Co., Ill., forks in a good dressing of manure in the Spring, and when the fruit begins to ripen he cuts the new shoots back to let the sun in, and also to induce side branches. The canes are in hills, four together, tied to a single stake. As soon as the fruiting is over, he cuts out all the old canes and the weak growth of the new, and forks in more manure. By this method he gets strong shoots for fruiting the following year.

Preserving Figs.—C. Pell, Wayne Co., N. Y. In the South of Europe the figs are simply dried in the sun, or, in wet seasons, in a heated room. They are turned frequently to insure equal drying. You think fresh figs insipid: we do not. The taste for them is partly an acquired one like that for tomatoes. We should like to breakfast with you if you could give us fresh figs and cream—you would not be troubled to dry them.

Hardiness of Plants.—John Walling, Clinton Co., Mich. The *Catalpa* is barely hardy here, and will probably not stand your winter. It depends upon the sort of magnolia you plant, whether it will endure. *Magnolia acuminata* and *glauca* may stand, and though we should not like to insure them, they are worth trying. It is impossible to predict about plants without actual experience. We have seen the Southern Cypress quite hardy in your State, while plants which naturally grow much farther north were killed. Clematis Virginiana grows wild in Michigan, and is hardy.

The Wistaria.—"J. W. R." Bath—(State not given.) If in Maine, the Winter is too cold in your locality. Try laying down the vine next Fall, and covering it with some litter and a few inches of earth.

Two Very Long Iron Bars!—We write this item in Central Iowa, at Grinnell, the farthest point west to which the Mississippi and Missouri Railroad is yet completed. Before our window lie two parallel heavy bars of iron, the ends meeting other bars eastward in one continuous line all the way to New-York City—over the prairies, through cities, winding among the hills, and crossing rivers on substantial bridges. A car loaded with the products of these fertile prairies can go through to the great Metropolis on the Atlantic, without being broken in bulk. We can step on board, and in 51 or 52 hours, traverse the whole distance, of 1196 miles! We occupied two weeks in coming here, as we made frequent digressions, but always returning to the main route. Here is the route: From Grinnell to Davenport, by the Mississippi and Missouri R. R., 120 miles; thence by the Chicago and Rock Island R. R. to Chicago, 182 miles; thence by the Pittsburgh, Fort Wayne, and Chicago R. R., to Pittsburg, 468 miles; thence by the Pennsylvania Central R. R. to Harrisburg, 249 miles; thence by the Lebanon Valley, the Eastern Pennsylvania, and the New-

Jersey Central Railroads, to New-York City, 177 miles. All these roads join so as to form a continuous line, and the trains connect, so that if in haste, one need not stop night or day, except to eat, for which time is allowed at suitable intervals. Commodious sleeping cars are provided in the trains running at night, and we have found a very commendable effort, on the part of all employed in running the trains, to make their passengers comfortable. It is worth a trip over this route to see the broad country on the way, and to see and enjoy these magnificent prairies. Thanks to the skill, and enterprise, which laid down these two very long iron bars!

Keeping Grapes.—S. Mitchell, of Steuben Co., N. Y., gives in the Rural New-Yorker his experience with several modes of packing Isabella grapes. They were all put in boxes one foot square and six inches deep, to admit three layers of clusters, and kept in a cool, dry cellar, so cool that water froze. Those packed in colored sheet-wadding—a layer of grapes, then wadding—kept tolerably well until the middle of December, when they began to rot and mould. Others packed in fresh-grape-leaves kept nice and plump until the last of December, improving in the meantime. They then began to mould badly. The best results were with grapes packed between alternate layers of newspapers. By changing the papers and repacking he kept grapes plump and fresh until used up March 15th.

Hybridizing Strawberries.—G. Pillsbury, Rockingham Co., N. H. This operation, which should properly be called crossing, is performed by cutting out the stamens of the flower to be fertilized, as soon as it opens, and then applying the pollen from the flower with which you wish to cross, by means of a camel's-hair pencil. If not familiar with the structure of flowers, the Boys and Girls' Garden for July will explain.

Mulching Strawberries.—W. H. Morgan, Harford Co., Md. The winter covering of strawberries should not be more than one or two inches thick over the crowns of the plants. Perhaps with you a very thin covering would answer as a protection against sudden changes of temperature. This Fall covering is designed not only to protect the plants during Winter, but to keep the ground around the roots moist during the Spring drouths, and also to keep the fruit clean and the weeds down. Forest leaves answer an excellent purpose as a winter protection, and we have known tan-bark, saw-dust, and shavings from a planing-mill, to be used with good results. The last-mentioned articles are disposed to pack closely, and should be put very thinly over the crowns of the plants. Strawberries do not so much need protection from the severity of Winter as they do from frequent freezing and thawing.

Cobaea Scandens.—Jos. Marsh, Wis. This is grown as an annual, but it is a perennial in the green house. You will be more apt to get flowers by starting new plants than by any treatment of the old ones.

Mushrooms.—J. Wickersham, Ind., is referred to the Sept. *Agriculturist*, 1861, for full directions for cultivation. The spawn may be had at the seed stores.

Stuffing Birds.—"Ignoramus" will find a brief article in the *Agriculturist* for October, 1862. The skinning is not difficult, but the setting up depends upon one's natural taste and eye for form. He can learn more from seeing an experienced taxidermist work a few hours than he can from any printed directions.

International Wheat Show.—We again call attention to the International Wheat Show, to be held at Rochester, N. Y., Sept. 8, 9, and 10th, at which samples from any part of the world will be admitted for competition. The large premium list, amounting to five hundred and forty dollars, is well worthy the attention of wheat growers. As there will also be an opportunity of selling good wheat at extra prices for seed, the inducements to contribute to the exhibition are in themselves sufficient to warrant a large show, aside from the fact that the interest of farmers generally will be greatly promoted by a comparison of the different varieties of wheat, and the selection of that best adapted for culture in the United States.

Fair of the American Institute.—The Thirty-fifth Annual Exhibition of this Institution is announced to be held at the Academy of Music in this City, commencing Sept. 3d, and to continue three weeks. A Horticultural Exhibition is to be had in connection with the general Fair, during the last week. Articles of every kind are admitted, provided they are of American manufacture. Inventors and manufacturers have an opportu-

nity at this gathering, of exhibiting their wares to very large numbers of visitors, and they usually avail themselves very largely of the facilities offered, so that in general the show is well worthy a visit.

Brakes in Pastures.—C. Crockett, Penobscot Co., Me., and several other subscribers. We know of no other way of getting rid of brakes, short of grubbing them up. The long root-stocks or underground stems are very indestructible; we have turned them up after they had been plowed under for several years, and they seemed to be as sound as ever. Drainage would doubtless render the land less suitable for them. There are but few ways in which any particular plants can be killed. The land can be rendered uncongenial as regards moisture; they can be crowded out by cultivated crops; they can be exhausted by repeated mowings, and they may be grubbed up root and branch. Besides this, thistles and burdock may be poisoned with salt. This is the extent of our present knowledge about exterminating particular plants. If our readers have any facts on the subject, we should be glad to learn them.

Marble Dust as a Fertilizer.—Wm. C. Chipman, Barnstable Co., Mass., and others.—Limestone, marble, and chalk are alike in composition, for they are each composed of lime and carbonic acid. The main difference in composition is the presence of a very small quantity of iron, or other metal, which darkens the limestone, and shades some beds of marble. The compactness, the degree of crystallization, and other causes, give a different physical appearance to the three forms of carbonate of lime. Burn limestone, marble, or chalk, to drive off the carbonic acid, and in each case you have caustic lime remaining. Grind or pulverize them, and in each case you have a powder which is chiefly carbonate of lime. On some soils entirely deficient in lime, the unburned powder may be beneficial, but we suspect not greatly so, from the fact that on soils filled with limestone, and even partly made up of the detritus of limestone, good results are derived from burning a part of the limestone, and applying it in this state to the soil. The expulsion of the carbonic acid leaves the caustic lime in a state to act more energetically as a neutralizer of acids in the soil, and as a decomposer of organic materials to fit them for plant food. The fact that air-slaked-lime, which is in a measure re-carbonated, is somewhat beneficial, would indicate that very finely powdered limestone, or marble, or chalk, should be of some value, though its comminution is infinitely less than when disintegrated by fire. Marble dust may be used on heavy soils as an ameliorator to change the physical condition, and to ultimately affect the chemical constitution.

Lambert or Weevil-proof Wheat.—Jos. Henderson, Mifflin Co., Pa., writes to the *Agriculturist* that this variety of wheat, which has been highly extolled in some quarters, has proved very inferior in his locality. Four years since, he and several neighbors procured and sowed 50 bushels. The heads were short and loose, and where the straw appeared as heavy as the Lancaster Bearded variety which stood beside it, the yield was at least one-third less. The latter kind is almost the only wheat now sown in that section.

Stock for the Michigan Agricultural College.—We were recently gratified by a short visit from our friend Dr. M. Miles, the Professor of Zoology, etc., in the above institution. He has been among the celebrated herds of the Eastern breeders, purchasing stock for the farm of the College. He purchased from Samuel Thorn, Esq., of Thorndale, the short-horn bull Fatalist and the cow Dicytra, and from F. M. Rotch, Esq., Otsego Co., N. Y., the short-horn heifer Haze. Also the following Devons from the herd of E. G. Failes, Esq., West Farms, N. Y.: the bull Cherokee and the heifers Zuleika 2d and Eveleen 5th. We are glad to learn that such valuable stock has been acquired by this College, an institution which has every element of success except the hearty appreciation of the farmers of Michigan, and this we bespeak for it.

Insects.—"J. T.," of Southport, Conn., sends us an insect which he says cuts off the leaves of his fig-trees. The insect is one of the Tree-Hoppers, and judging from the rather imperfect specimens, is not a species common about here. We think that the leaves must be eaten off by something else, as these insects live entirely by sucking the juices of leaves and tender twigs. The young insects live in the ground, upon the tender roots of the tree, and it is in this state that they do the most damage. No remedy has been proposed, to our knowledge. John Chislett, of Alleghany County, Pennsylvania. The insects were, as you supposed, the too common Rose Bug. As the eggs are laid in the ground and the grub subsists there until it comes out a perfect beetle,

there is no time at which it can be successfully fought, save in its perfect state. Jarring them from the trees on to sheets and then destroying them, is the only feasible remedy we have seen proposed. If half the insects destroyed in this way are females, the crop for the next year will be much diminished. Birds destroy many of them, and they are devoured by fowls as they are about to enter the earth to deposit their eggs.... The specimens from A. L. Child, Cass Co., Neb., were *Doryphora decemlineata*, or the Ten-striped Spearman. It is a beetle which has of late become very troublesome in Iowa, Nebraska, and other far-Western States. They are particularly fond of the potato and tomato, but in the absence of these will devour any green thing. The eggs are of a red color and are laid upon the leaf, and the sluggish grubs which come from them, eat with great avidity. Several generations are produced in a season. The grub undergoes its transformation in the ground, and comes out a perfect beetle, about half an inch long and about as broad, of a pale yellow, with 10 black lines on the wing-covers. The principal damage is by the larvæ. Mr. C. finds that by hand-picking he is able, with great labor, to reduce their number. We as yet know of no other way to treat them.

Insects on Wheat.—John McKibben, Walworth Co., Wis., M. H. Taylor, Walworth Co., Wis., and W. E. Abbs, Fond du Lac Co., Wis. The insects forwarded are the grain aphids, which appeared in countless numbers upon grain, especially oats, in many of the northern States, last year. They do considerable injury by sucking the sap of the plant and making the grain shrivel. This year they do not appear to be as abundant. We know of no means to prevent their ravages. They have several natural enemies to keep them in check, the principal one of which is the small insect known as the lady bug, or lady bird (*coccinella*.)

Lice on Cattle, etc.—Demarest, of Essex Co., N. J., finds that the "Insect Powder" commonly sold, destroys lice on cattle. He rubs it along the back of the animal and works it down to the skin, and in the same way on the head and face. It is also good for fleas on dogs, and to keep lice away from setting hens; for the latter purpose he sprinkles it over the nest several times during the period of setting. This powder, which was formerly put up by some parties as a secret article, is now for sale in bulk at the drug-stores. It is mainly, if not wholly, the powdered leaves of a European species of *Pyrethrum*.

Slobbering in Horses.—Francis E. Rumford, Newcastle Co., Del., writes to the *Agriculturist*, that cabbage leaves fed to horses occasionally, with a little salt, will remedy slobbering.

Hardiness of Apple Trees in Illinois.—"J. H." writes us from Washington Co., Ill., that of an orchard of 3500 trees set out in 1859 and '60 he found about 600 damaged by frost. Perpendicular cracks, 1 to 3 inches long, appeared at the base of the trees, and some of them had three or four of these cracks, and the bark apparently dead for ten inches above the ground. He filled up the dirt to the height of 12 to 18 inches around each of the diseased trees and, by the middle of July, new bark had formed under the old, and by this treatment he saved all but some 50 or 60 of the affected trees. The varieties which suffered most were Prior's Red, Roxbury Russet, and Caroline Red, the latter being injured badly. Rawles' Jannet, Summer Queen, Fall Pippin, and Wine Sap were slightly injured, and Red June, Early Harvest and New-York Pippin were all sound.

Pears which Rot at the Core.—Mr. H. Morgan, Harford Co., Md., asks if there is any remedy for pears which become "mushy" while they are fair outside. This is one of the faults of otherwise good pears and there is no help for it. Better graft the trees over with sorts which are free from this bad habit.

Crops and Things in Decatur Co., Indiana.—John W. Smith says: It has not been so dry here for several previous years. Our wheat crop was good; our corn would make a pretty fair crop if it had rain; our oats were very good; our early potatoes are good but late ones are poor; peaches and apples are plenty; no quarreling among neighbors; our Union men are in the best of spirits; our Copperheads down in the mouth; our ladies industrious and—pretty of course.

Soap Suds for Blackberries.—L. Farnsworth, Ashland Co., O., writes to the *Agriculturist* that last season Lawton blackberries were almost worthless from a severe drouth occurring as they were about maturing. This year drouth occurred again in that vicinity, but he gave the blackberries the suds left after wash-

ing every week, and the yield was superior to any thing of the kind he had ever before seen.

Fuller's Seedlings.—C. Saunders, Mo., asks our opinion of the Col. Ellsworth and Monitor Strawberries, as he saw they were not noticed at our exhibition. These berries had already been exhibited at two shows, and Mr. F. having other new sorts, did not care to bring in the above varieties. The vines are all devoted to making plants, and are not allowed to fruit.

"Minnesota Flax."—Richard Chute, Minn., sends us a sample of a fibre with the above name, the product of a native plant which we cannot name, without leaves and flowers. The fibre is quite fine and strong. We have no means of judging of its market value. That probably could not be told until its value had been tested. The sample given to a party interested.

Plants for Names.—L. H. Andrews, Marshall Co., Ind. *Connelyna Virginica*, which may be called Virginian Day-flower, for a popular name. Also *Hypericum prolificum*, Shrubby St. John's Wort—a fine plant, and worth cultivating.... Mrs. S. B. Morris, Portage Co., Ohio. The plant, as near as can be judged from the specimen, is *Neiremburgia gracilis*, a good bedding and house plant. The "Flowering Maple" she asks about is probably the *Abutilon*, figured on another page.... J. H. Ferguson, Rensselaer Co., N. Y. The plant sent is the Trumpet Creeper, *Tecoma radicans*, (called *Bignonia* in the catalogues.) It is one of our most beautiful climbers, and is a native of Pennsylvania and southward. It is quite hardy around New-York. The specimen came in perfect order, being nicely packed in a tin case.... J. G. Foster, Riley Co., Kansas. The specimen is *Ipomoea leptophylla*. As it is not generally known, it has no common name. It might be called Willow-leaved Morning-Glory. It is a perennial species of Morning-Glory with a large fleshy root. We should be glad of a few seeds.... G. Hurd (place not given) sends *Similax Pseudo-China*, a species of China Brier.

Lemon Buds.—J. C. Laing, Tuscola Co., Mich. You can get them of almost any good florist. Isaac Buchanan, of this city, would furnish them.

Sending Insects.—We frequently receive insects to be named, but they generally arrive in such a crushed condition that it is impossible to make them out. We again ask those who send us insects, to enclose them in a small box or in a goose quill. Those arriving in good condition will be reported on as soon as practicable.

Do Dahlias Change Color?—So asks John W. Cook of Ottawa Co., Mich. We never knew a self colored dahlia (i. e., all of one color) to change, but we have known a purple tipped with white to produce flowers all purple and all white, especially among the first blooms of the season, and this may doubtless happen with other marked sorts.

A Non-blooming Rose.—A Lady Horticulturist in Utica, N. Y., says she has a Giant de Battailles rose which will make nothing but vigorous shoots and leaves, and asks what is the reason. As all her other roses do well, we cannot suppose soil and situation have anything to do with it, and venture the guess that she planted a budded bush, that the budded portion died out, and that the rampant portion sprang up from the stock.

Room in an Ice-House.—H. H. Bechbel, Juniata Co., Pa. Schooley's patent preservative, described in the *Agriculturist* volume 17, page 120 (April No.) is an arrangement by which a room in an ice-house is kept cool for the preservation of provisions, fruit, etc. This or some modification of it would probably accomplish the object you desire.

Wine-making.—We have several letters asking for directions for Wine-making. In September, 1862, we published an article on this subject as full as our limits would allow. In the present crowded state of our columns we cannot republish it, but have extra copies on the usual terms. The subject is too extended for a paper like this; we should be obliged to devote all our pages to it, in order to describe all the details. To those who wish to go into wine-making extensively we say that they cannot do better than to buy "Haraszthy's Grape Culture and Wine-making." This gives all the European processes, and though the price is rather high, they will perhaps save by it in the end. Price \$5, for which we can send it post-paid. It is fully illustrated.

Work on Bees.—C. J. Atwater, Ontario Co., N. Y. Quinby's "Mysteries of Bee-Keeping" is a good, practical work on the subject. We can forward it post paid on receipt of the price, \$1 25.

A Visit to the Largest Farm in Our Country.

The latter part of July we visited, near Bloomington, Illinois, our friend Albert Todd, who was formerly connected with the N. Y. Daily Times, but who has partially laid aside the pen, and is now knowing from actual experience what it is to be an independent western farmer. (We almost envy him his beautiful prairie home, his great corn fields, and his sleek corn-consumers that grow in flesh and money value, while the proprietor sleeps, as well as when he is awake.)—Among other things planned by friend Todd, for our pleasure and profit, was a visit to the great farm of Isaac Funk, a few miles southwest of Bloomington. Everybody knows Isaac Funk, the plain farmer, whose soul-stirring, impromptu eloquence, so electrified the Illinois Senate last winter. That speech has since been printed in hundreds of newspapers, and tens of thousands of copies, on cards and handbills, have been circulated all over the country, and are yet posted up in thousands of shops East as well as West. It did us good to grasp the hand of the Kentucky-born farmer, who, like President Lincoln, wandered in early life to the wild prairies of Illinois, there built up a fortune, and in these latter days has gained a wide reputation by his noble stand for the preservation and perpetuity of our glorious Union.—Fortunately, as we set out on the day's trip, we met Mr. Funk, in Bloomington, bound homeward, and had the pleasure of riding with him in his plain farm wagon. In the familiar conversation on the way, we learned from him the history of his early life, his struggles with poverty, and his gradual success, from the time he emigrated to Illinois nearly forty years ago, with but a few dollars in his pocket, until now, when his landed estate covers an area of full *forty square miles* (25,650 acres!)

We have space but for a few of the more interesting items. Mr. Funk arrived in Illinois, and commenced work in 1824. In 1826, he gathered up 110 head of cattle, and started with them for a market in Ohio, about 450 miles distant, much of the route through the woods of Indiana, and Western Ohio. They were 31 to 32 days on the road. The drivers rode on horseback, carrying their provisions, and camping out with the drove. The first price realized for the cattle was \$9½ per head, and afterward it gradually rose to \$12½, and then to \$15, and the droves were increased to from 200 to 250 head. To make up these droves, several settlers turned in their cattle and received an agreed price, or a proportion of the sales, on the return of the drover.

As fast as the results of these enterprises, and of raising and feeding cattle, furnished the means, Mr. Funk purchased land at the government price of \$1.25 per acre, and about one-third of his present estate was secured on these terms. The other two-thirds have been purchased of others, at prices ranging from \$2½, up to \$30 per acre. Mr. F. has paid the Illinois Central R. R. Company alone, some \$80,000 for portions of their land lying adjacent to his original purchases. We entered upon the main farm some six or seven miles southwest of Bloomington. This consists of 20,500 acres, in one tract, longest from East to West, with farms owned by others jutting into it at several points. (The balance, about 5000 acres, is located a few miles east and northeast of Bloomington.) The general character of the main farm is prairie, but there is abundant timber along Sugar Creek, which runs through the estate in a southwest direction,

and which, with its branches, furnishes an abundant supply of living water for the stock, throughout the driest seasons. The surface is rolling, and the sloughs (pronounced sloos), are so located that nearly the whole can be drained; indeed they are so inclined that nearly the whole surface is naturally drained. This feature, together with the woodland, the running water, and the general fertility, render the whole tract one of the best in the State.

About 3000 acres are devoted to corn, and a small portion to other crops, including improved grasses; the great bulk is in natural grass pasture. The corn land is mostly let out on shares. The cultivators usually return two-fifths of the crop for the use of the land, including certain other privileges, and Mr. Funk then buys their three-fifths. This is generally taken in the field, unhusked. A few average shocks are selected by the two parties, and husked, and the whole number of shocks are then counted, and reckoned in bushels by the product of the husked ones. The price is fixed by the average price of corn in the country, for 8 or 10 miles around, or at 2 to 3 cents per bushel below the value of *shelled* corn, at the nearest market town.

The main business of the farm is the pasturage and feeding of cattle for beef. These are purchased from the surrounding country, pastured for a season, fed with corn in the winter, and the next season sold to dealers to go to distant markets—usually N. Y. City. Mr. Funk says he finds it most profitable to buy only the best cattle. Generally, however, he is obliged to take them in lots. In this case the best are fitted for market first, and the smaller and poorer animals are kept a year longer. A few cattle are raised on the farm. We noticed one "little bunch" of 150 cows with their calves. The calves run with their dams, and have all the milk. Only good cows are used for this purpose; the sires used are ¾ or ¾ Durhams (Short Horn). Generally, Mr. F. buys cattle to use up most of his pasturage, but sometimes, when cattle are high, and the future price of beef quite uncertain, he takes in a few hundred or thousand cattle to pasture, at 30 to 50 cents each per month. He keeps four to five hundred hogs, or just enough to eat up the waste corn left by the cattle, to which the corn is fed on the stalks. He has only eight or ten hundred sheep at present, and some 300 horses and mules. About 60 mule colts are raised each year. The breeding mares are not put into harness at all.

The cattle are sorted into droves of similar ages, about 200 in each drove. The pasture fields are so arranged as to have running water in each. The animals are salted twice a week; the salter taking two or three barrels upon a wagon, drives out to the herds, and scatters the salt upon the ground, spreading it so much that the weaker animals shall have free access to it. Though we are accustomed to see three or four thousand head of cattle in the yards on market days, we were much interested in observing a herd of two or three hundred come scampering across a field at the familiar call of "po-o-o, po-o-o," to receive their expected salt rations. And such fields! 500 acres in one; 1000 acres in another; 1500 acres in another; and 2500 acres (2 miles square, or 4 square miles,) in another single field! That is certainly farming on a large scale. As a rule, we believe in small farms—50 to 100 acres is as much as most men will or can cultivate with the highest profit—but it is gratifying to, once in a man's life, see a farm like Isaac Funk's. If an agriculturist himself, one feels that he belongs to a class which

numbers its princes and magnates. Mr. Funk says he has done buying land—feels that he has *enough*! He has eight sons and one daughter to share his possessions, and will be able to give each one a "right smart" farm. Two or three of these are erecting dwellings on the estate. The father retains his simple habits and dress, is social and familiar in conversation, and still occupies the plain frame dwelling which has been his homestead for twenty four years past. He is enthusiastic in the belief that our great country is to be restored to its former Unity.

We shall not soon forget the pleasant day passed on the great prairie farm.

Free Homes—Who may get Them, Under the Homestead Law—How to Do it.

An article in the July *Agriculturist* upon the working of the Homestead Law, having called out a great many written and personal inquiries, we requested a friend in the Department at Washington, to make us a plain and brief statement of the provisions of the Law, which we publish for the benefit of those who wish to take up homesteads upon the public lands.

I. The persons entitled to free homes, on unappropriated public lands, are: Any person who is the head of a family, or who has arrived at the age of twenty-one years, and is a citizen of the United States, or who shall have filed his declaration of intention to become such, as required by the naturalization laws of the United States, if he has never borne arms against the United States Government or given aid and comfort to its enemies; and any loyal person, of whatever age, who has rendered not less than 14 days' service, during actual war, in the Army or Navy of the United States.

Proof of these conditions to be made by affidavit before the Receiver or Register of public lands, in the section where it is desired to make the location. The names of these officers can be readily learned in any desired locality.

II. Any such person may take up, for the actual occupancy by self or family as a homestead, not more than 160 acres of public lands valued at \$1.25 per acre, (or 80 acres valued at \$2.50 per acre,) located in one body, and the boundaries agreeing with the usual subdivisions of public surveys—as follows:

1st, Select the land that is regularly surveyed, and present the following application, with \$10 to pay survey, and usual fees (about \$1), to the Receiver, who will administer the proper affidavit and receipt the money.—On presenting these, the Register will enter the application and file the affidavit.

Form of Application.—"I, [A. B., of town, County, and State,] do hereby apply to enter, under the provisions of the Act of Congress, approved May 20, 1862, entitled "An Act to secure homesteads to actual settlers on the public domain," the — of section — in township — of range —, containing — acres."

These blank forms, and necessary information, are furnished by Receivers and Registers.

2d, Not less than 5, nor more than 7 years after entry of application, the applicant will make proof by affidavit and two witnesses, of residence on or cultivation of such homestead for five successive years after the application—that no portion has been sold or otherwise parted with—and that the applicant remains loyal—when a certificate for a full ownership deed (or patent) will be granted by the Register, on payment of the usual fee (about \$1); the deed may then be procured from Washington, D. C.

3d, In case of the claimant's death, the widow or lawful heirs are entitled to the homestead by completing the conditions. If the heirs are infant children, it may be sold for their benefit. But it can not be sold at any time for any debt contracted before the patent (or certificate) was granted. Any abandonment of the homestead by the applicant, for more than six months at a time, forfeits the claim for the patent.

General Average.....	1-5	1	1	1	1	1	1	1	1	1	1	1

In the accompanying tables, the injury is represented directly, thus: 1 means an injury to the extent of one-tenth of the crops— $\frac{1}{2}$ means one-half of one-tenth; instead of by 9 and 9½. The injuries were so small in most cases as to be but fractional parts of one-tenth, and in order to present them more directly to the reader, the change was made.—In the appearance of crops, the former method is preserved. Thus: 10 being an average, 9 is one-tenth below it, and 11 one-tenth above it. The amounts of the crops of Wheat, Barley, and Wool, are not given, as they will be reported more fully in succeeding months, when the results of the harvest are more fully and definitely ascertained.

The Crop Prospects—Unusual Weather.

At no other time within our recollection has it been so difficult to form a correct estimate of the actual condition of the growing crops, or of the actual yield of those just harvested. This difficulty arises from the fact that the season, thus far, has been remarkable for the variety of weather in different parts of the country, and even in localities but a few miles apart. Within the boundaries of a single State there was an abundance of rain all through the Spring and Summer, while at points but little distant, a parching drouth dried up the grass, and kept back the corn and the grain crops. Again, in some parts of Ohio, for example, the harvest weather was as fine as could be desired, while in portions of New-York it was next to impossible to gather wheat and oats, and the later hay crop, for want of a few drying days. The difference referred to above, was very marked in going a distance of 1,200 miles westward from New-York City, to the centre of Iowa. At one point the corn was in most vigorous growth, while less than a hundred miles further on, it was tasseling out near the ground, through lack of moisture to carry the stalks up to the usual height. It would require too much space to specify the condition in each locality. The accompanying tables, which give the results of a large number of observations, gathered from all over the country, will afford some idea of the crops, etc., up to the close of July. The last column in the second table shows a remarkable difference in the rain-fall in the several States. Thus, in Connecticut it was over 11 inches, while in Minnesota it was but five-eighths of one inch, and in Kansas less than one-eighth. Throughout New-England the rain fell in July 7 to 11½ inches, while in the Western States it seldom reached 4 inches, and was generally below 3 inches. In Kentucky nearly 7 inches fell. In New-York there were 18 very wet days reported for July alone.

Of the crops as a whole, judging from personal observation, and from information gathered from a great variety of sources, we estimate the yield of wheat (Winter and Spring) to be but

NOTE.—The explanations to the table above, apply equally to this.—The Weather Notes are of especial interest.

a trifle below the average of other years, but the deficiency not equal to the amount of last year's crop still on hand, so that there is enough to meet all home requirements and the probable foreign demand. This last item is very uncertain. If peace continue in Europe, the call upon us for breadstuffs will not be very large. Should the present disturbances in regard to Poland result in a war between Russia and the Western Powers, it will lead to a large demand for our Agricultural products, and materially affect prices here. At present the prices at the seaboard are dependent mainly on the rise and fall in gold, as noted on page 282 of this paper. At present the nominal prices of nearly all agricultural products, especially grain and wool, are tending downward quite rapidly, the price of gold having fallen from 174 to 124 since the first of March last. The prospect for an early and successful close of the war is still further reducing the gold premium.—The Oat crop has

turned out better than was feared at one time, though poor as compared with former years. In some places oats have failed almost entirely. The warm weather and frequent showers of August thus far, have pushed forward corn very rapidly, and if early frosts do not interfere, the general yield will be fully up to, if not above an average. Potatoes are filling up well in the hill. Beans are much more largely planted this year than ever before, and bid fair to turn out a good yield. Hay will be abundant in some localities; in others there will not be enough to winter over the usual amount of stock. It would be desirable to transfer part of the neat cattle from the latter to the former sections of the country. We recently saw large numbers of sheep in Iowa brought from the drouth regions of Michigan. The Apple crop, though very good in a few places, will be quite below the average throughout the country; there will be a good demand for all that can be saved by drying.

The New Tea Substitute—or "New-Jersey Tea."—(*Ceanothus Americanus*.)

Several readers ask for some account in the *Agriculturist*, of the plant which has been spoken of in other papers as affording a good substitute for tea. We intended to do this before, but a press of other matter has crowded it out until rather late in the season. The plant in question is *Ceanothus Americanus*, or "New Jersey Tea." We are not able to trace out the meaning of the botanical name, *Ceanothus*, but its common name, New-Jersey Tea, is given it for the reason that it was used in New-Jersey as a substitute for tea, during the war of Independence. It is one of the common shrubs of our dry woodlands, and is found throughout the Northern States. In Europe it is cultivated as an ornamental plant, and if it should prove to be an object, there is no doubt that plantations might be readily established. Our engraving represents a flowering branch of the shrub, which is low and bushy, and from one to three feet high. The stem is of an olive green below, striped with markings of brown, while the young shoots are of a lively green which turns to brown on drying. The leaves are 2 to 2½ inches long, by 1 to 1½ inches wide, with three strong ribs; they are on short foot-stalks, and are smooth on the upper surface, and a little downy on the under side. The flowers are very small, and are borne in dense white clusters at the end of long downy foot-stalks, which come from the axils of the upper leaves. The flowers are followed by a dry three-sided pod, which bears three seeds. As mentioned above, the leaves were formerly used in place of tea; now that the high price of tea and coffee leads those accustomed to these articles to look for some substitute, it is quite natural that the New-Jersey

Tea should come again into notice. We trust that our engraving and description will enable those who wish to try the experiment, to identify the plant. As to the quality of the article, the only special information we have is from John Salmon, Esq., of Clinton Co., Pennsylvania. He considers it equal to the imported tea. He says that in one township in his county there is a manufactory which employs a Chinaman to manufacture the "tea," and that they now have about a thousand boxes on hand; that he has used it for a year past, and considers it equal to the best black tea from China. Mr. S. thinks that if adequate capital and skill were engaged in the business, we should be able to produce our own tea. We give the statement as it comes to us, without any further knowl-

edge on the subject than what is presented above. Except for old tea-topers, this substitute may answer as a "warm drink." We frequently hear from those who profess, and doubtless think that clover tea is more delicious than anything from China.

Plan of a Farm House.

The accompanying plan of a house, which has some good features, was contributed to the *Agriculturist* by "W," of Mount Hope, N. Y., who writes: "Having built a house about a year ago, I am aware of the difficulty one has in selecting a good plan. At least in my case it was difficult, for I wanted the most rooms and in the most convenient positions, at the lowest cost. I examined such works as Downing's, Baekus's, etc., as well as my files of the *American Agriculturist* and *Country Gentleman*, but found none that would suit my views without costing more than I felt willing to pay. I very soon came to the conclusion that the nearer square a house is built, the easier can it be divided and retain the great advantage of easy access to the different apartments. Every step saved to the women is so much less wear of patience and disposition. In the accompanying plan, the hall is in the centre and runs from the front door, (which in my house has two long glass panels), to the kitchen. Opening off the hall on the right is the dining room or living room; while opposite, on the left is the parlor. The parlor is only 14.2x13.9 to admit of having a good sized bedroom in the rear of it—for I hold that the parlor is generally the most useless room in the house, if the living room is properly attended to, that is, for us who reside out of town. The bedroom has a door from the parlor and also

one into the kitchen. The dining room has one door from the hall and one into the kitchen, and the kitchen has one from the hall, one opening on the back stoop, and also a store room about 7x6, and a water closet 5x6 opening off from it. This last arrangement was greatly objected to by many, in fact nearly all who saw the plans, or the house while building [and for good reasons, we should say.—Ed.] In practice I have found no trouble, but great convenience from

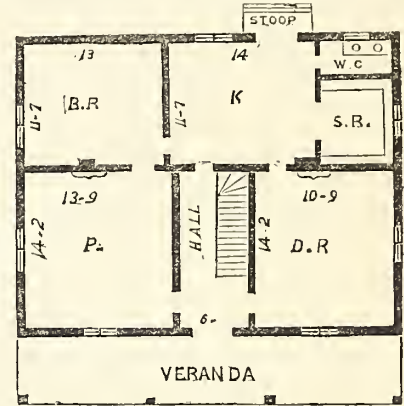

Fig. 1.—GROUND PLAN.

the arrangement. I had the foundation wall left open for about 4 feet and built so as to come under the double partition between the water closet and the store room, forming the sides of solid masonry, and the bottom also was made of stone. The opening of the foundation wall is fitted with a door and casing, and it has earth thrown in every week or two, and the entire vault cleaned out once a month, and the contents removed into the manure shed. With this method there has been no manner of offence to the eye or nose. The inside is lined with water cement—and, as said before, the partition between the closet and the store room, is double.

The stairway from 1st to 2d floors has a closet under it—though if the cellar was under the whole house I should have the cellar stairs there. I had a small cellar built for my house, the wall crossing the house under the partitions between the bedroom, kitchen, storeroom, and the parlor, hall, dining room—also serving to support the two chimneys which are made so as to have a flue from each room for stoves, and also one for ventilators.—There are four good

Fig. 2.—SECOND STORY.

sized bedrooms on the second floor, with two large closets, and from the back bedroom on the right, a door opens to the cupola stairs, under which stairs is another closet. You will perceive that each room is capable of receiving very thorough ventilation, and the furniture can be arranged in each bedroom without having a bedstead cross either window or door.

After living in this house a year or more, we have not found any fault with it, except in regard to the cellar not extending under the whole house. This, however, can be easily remedied."

Farm Animals Wanted in Kansas.

The following extracts from a letter to the *American Agriculturist* from F. O. Black, of Shawnee Co., Kansas, will be interesting to farmers having large stocks of cattle and sheep, and a limited supply of fodder for the coming Winter. He says: "I wish to bring before the minds of the people the importance of converting the grass in the West, into sheep, cattle, and horses. Without doubt there will be grass enough burnt this Fall and Winter to clothe our army, if it could be made into wool. Millions of acres of as fine grass as was ever seen, are now growing here. Kansas is one vast prairie. It is the Atlantic of the United States pastures. The banks of the streams are lightly fringed with timber; there is stone in nearly every locality in great abundance for building and fencing; stone-coal in abundance for fuel, and salt works are rapidly progressing. Now the question is, how is this great work to be accomplished? We are not able to purchase the stock. Most of us brought some means with us; we brought oxen and plows, and commenced on quite an extensive scale for the amount of means employed. We thought we could raise grain in great abundance, but for some reason we have not done so; the grain business has been a failure. Stock has always done well, and those that engaged in raising it, have made money. Those that went into grain growing, worked harder and made money out of pocket. Nine-tenths of the farmers west of the Missouri River will vote this same ticket, unless I am greatly mistaken. There are great quantities of stock grazing on the eastern pastures where grain could be grown to a great advantage. Now if the gentlemen will lend us a listening ear (the ladies will not be excluded, for we need many of them here as well as stock,) and send us animals, we will take care of them on as reasonable terms as it can be done anywhere. Some would prefer horses, some cattle, some sheep. Perhaps the latter would be preferable, as the grass in that shape would be easier transported and cost less. I would take two thousand head of sheep, and give two lbs. of wool per head, and return the original stock; or I would give half the wool and half the increase for a term of five years or longer. I presume that there could be fifty or a hundred thousand head of sheep let in Kansas at these rates. This speculation will pay much better than investing in wild lands."

Swelled Legs in Horses.

This disease takes on several forms. Sometimes it is simply a slight enlargement of the larger muscles of the legs, consequent upon standing on a hard floor, with lack of exercise. This often occurs when a horse is first taken in from pasture and confined in the stable. The obvious remedy is a little hard rubbing of the affected parts, feeding with grass or other light food, and plenty of daily exercise.

A worse form of this is when a horse, somewhat feeble and diseased in other parts, suddenly develops swollen limbs. This is apparently the shifting of disease from the other organs. It is accompanied with a lack of healthy circulation, with fever, soreness, and lameness. Sometimes abscesses are formed, and the heels are affected with "scratches." The treatment required is a mild physic and bleeding, if the horse is not much reduced. Warm bathings should be used, and bandages. If this trouble arises

from weakness and low living, the horse should have better food, and all means should be tried to improve the tone and vigor of his system.

How to Raise Potatoes Cheaply.

T. Hudson, La Grange Co., Ind., writes to the *American Agriculturist*: "My venerated father used to advise the application of team power in farming, whenever it could be done advantageously. Following his counsel, I use my team in planting and digging potatoes—almost in hoeing them. My method is this: When the ground is mellow, with a single shovel plow I run furrows about 3 or 4 inches deep, and 3 or 3½ feet apart, one way. I cut the potatoes, if large, and drop them 12 or 15 inches apart in these furrows. Then, with a two horse plow, turn a deep furrow over them. Let them remain in this condition until the young weeds show themselves, and before the potatoes make their appearance—usually in about 8 or 10 days—and harrow the ground level. A warm pleasant day is best. This destroys an army of weeds. On sod ground, I usually take every third furrow, and where there are no openings between the furrows, punch holes with a pointed stick about the size of a handspike, and drop the potatoes in these holes and openings, being careful to get them the proper depth. This is soon accomplished. Then harrow thoroughly. If weeds appear before the potatoes come up, harrow again. Afterward plow and hoe as usual. Hoeing will be a light task. The last plowing can be done with a single shovel plow, one furrow in a row, which will form about all the hilling necessary, without the use of the hoe, except to destroy the few weeds that remain.

In digging, plow one furrow through each row, spending no time to pull tops, pick up all that show themselves, and take out the remainder with the hoe. I estimate the raising and harvesting at about one half the labor required in planting in hills, and digging with the hoe."

Rotation or Change of Crops.

A subscriber to the *American Agriculturist*, at Somerset Co., Md., writes: "I have about 80 acres of medium quality tillable land. Soil, a sandy loam. One half is in corn. The other half lies fallow, with a natural growth, quite thick and green. According to the system of planting prevailing in this Peninsula, this fallow ground would be put in corn next year, and the other part lie out to recruit itself with its natural growth. I find that so much corn makes exhausting work, and I think such a system of tillage is gradually impoverishing the soil.

I think I could do better, as follows: Suppose I turn under my present fallow ground, while it is yet green; harrow it well; drill it with wheat, and immediately after give it a top-dressing of lime. Leave enough ground, however, of this half, to sow down in oats, to make grain for my horses. Then next Spring, sow the whole half with clover. At the same time flush up the other half, and put it in some better grass (timothy or clover) than its natural growth, to be cut in the Summer and cured for stock, and then turned under in the Fall to receive wheat and oats, and thenceforth to continue one half in wheat and oats, with clover, and the other half in clover for cutting, and turning under. It seems to me that this system would make vastly less work (especially if having all necessary machinery,) and would also rapidly

improve the soil, and exterminate the weeds."

REMARKS.—Probably the proposed change of treatment would be an improvement. The light growth of grass and weeds ordinarily springing up on a summer fallow, is a very inadequate return to make to land from which a crop of corn is gathered every alternate year. Corn is a strong feeder, and must draw heavily upon the original productive elements of the soil, unless there be added something to replace what is required for the growth of the crop. Under such a system the fertility of the land will deteriorate year by year, until it becomes "worn out," as is seen in thousands of acres in Virginia, where unintermitted cultivation of tobacco has drained the soil of its fatness, and left it too poor to pay for plowing, until brought into condition by the addition of fertilizing material. But the plan suggested, may be still further improved by the introduction of stock to feed off the clover during the season after the wheat and oats have been harvested. They will give a good account of the food they consume in the weight of beef added to their frames, and also in the manure which they have scattered over the fields. This will more rapidly bring up the condition of the land, than removing the larger part of the growth, by cutting and curing. It will also be fully as profitable to buy stock in the Spring, fatten, and turn them off in the Fall, as to cut the clover for their consumption in Winter.

The International Fair at Hamburg.

This great exhibition was formally opened according to announcement, July 14th, amid the most enthusiastic demonstrations. The various departments were well represented, but the show of animals was unusually large and fine. The exhibition of sheep, particularly, was the best and most extensive ever seen in Europe; more than seventeen hundred head were entered. It is gratifying to know that although the American contribution to this department was small, it was such as to excite no little admiration, and even envy, on the part of the sheep breeders of Europe. The specimens consisted of twelve animals from the flock of George Campbell, Esq., of Vermont, and to these were awarded no less than three prizes, viz: the first prize for buck of best quality, the first prize for the buck yielding the greatest quantity of wool, and the second prize for the best ewe, considering both quantity and quality. The amount of the first prizes is fifty thalers each, equal to thirty eight dollars in American gold. The correspondent of the Tribune writes that this entry of twelve American sheep was made public through the press of Germany several weeks before the Exhibition, and it was regarded as a great joke that America should for a moment think of competing with Germany in sheep. But the competition has been eminently successful, and the long faces of the other exhibitors indicated their mortification and disappointment. Open dissatisfaction was expressed that two of the first prizes for sheep should be awarded to America, and to settle the matter, Colonel Needham, Commissioner from Vermont, proposed a sweepstakes of one hundred dollars for the heaviest fleece, taking into the account the weight of the sheep, the jury to be appointed by the Association, the sheep to be sheared. But the German and French Exhibitors declined the proposition, thus practically affirming the justness of the award. The following is the list of prizes awarded to

Americans so far as heard from to August 5th:

LIST OF AMERICAN PRIZES.

George Campbell, Vermont, fifty thalers for largest quantity of wool.—1st prize.

George Campbell, Vermont, fifty thalers for largest staple.—1st prize.

George Campbell, Vermont, twenty five thalers for combination of quantity and quality.—2nd prize.

Cyrus B. McCormick, Illinois, gold medal for the introduction and perfection of practical mowing machines.

Seymour, Morgan & Co., New-York, large Silver Medal—for first-class Reaping and Mowing Machine.

Thornton & Avery, Pa., Silver Medal—Horse-Power.

James A. Saxton, Ohio, large bronze Medal—for improved Harrow and Cultivator.

Whittemore, Belcher & Co., Mass., large bronze Medal—assortment of Agricultural Implements and Machinery.

L. P. Rose, Michigan, large bronze Medal—for elegantly finished implements.

E. C. Tainter, Massachusetts, large bronze Medal—for planing and tenoning Machine.

George Campbell, Vermont, large bronze Medal—for Willard's patent Root Cutter.

John Vanderbilt, New-York, large bronze Medal—for Agricultural Implements and Machinery.

J. W. Free, Ind., large bronze Medal—Fanning Mill.

Hall & Spear, Penn., bronze Medal—splendid Plough.

S. P. Hubbel, N. Y., large bronze Medal—Seed Sower.

Cultivation of Tobacco.

The Essays on this subject which were received at the *Agriculturist* Office in response to our offer for premiums, and which have been published in pamphlet form, undoubtedly form the most valuable practical work upon the subject ever issued. Each of the different writers contributes some items from his own experience. The book costs only 25 cents, post-paid, and should be in the hands of every grower of tobacco. As a partial help to those not having the complete work, we give here some seasonable extracts from the essay of Mr. Oliver T. Bishop, Hartford County, Connecticut.

TOPPING.—Cultivators do not agree as to the time and where to top the plants. Some favor the plan of topping as soon as the blossom-buds appear, others prefer to wait until in blossoms. I think there is no harm in letting the *earliest* plants bloom before being topped, but after once beginning, they should be broken off as soon as the buds begin to look yellow, and the latest plants as soon as the buds appear. A beginner will be apt to top the plants too high. The object is to ripen and develop as many leaves as the plant can support; if topped too high, the top leaves are small, and when cured are nearly worthless, and the other leaves are not as large or heavy; whereas, if topped too low, then you lose one, two, or three leaves, which the plant might have supported. As a general rule, a plant just in blossom should be topped down to where the leaves are full seven inches wide, leaving on the stalk from fifteen to eighteen leaves. This will leave the stalks about two and a half feet high in good tobacco. Later in the season, top the plants sooner and lower. Let as many of the earliest plants as will be wanted remain for seed. One plant will furnish seed enough to put out five acres, at least. These should be wormed and suckered like the rest, only leaving the suckers above where you would ordinarily break it off, were you to top it. The plant should now be looked over every other day, to break off the suckers and catch the worms. This should be done as soon as the dew is off in the morning, and towards night, as the worms are eating then, and can be found more readily, while in the heat of the day they remain hid. Great care should be taken not to break off the leaves while going through; if broken they are mostly wasted before the crop is ripe.

SUCKERING.—As soon as the top is broken off, the sap is thrown into the leaves, causing them to expand rapidly. In the mean time suckers will start out just above where each leaf joins the stalk; these must be broken off, or the growth of the leaf will be checked, as the sap will be thrown into these young sprouts. Those nearest the top will start soonest, and will require breaking off twice before the plant is ripe; those at the bottom must all be broken off. This is the hardest and slowest work of all. Not only will these suckers check the growth of the plants, but if allowed to grow, will soon break or pry off the leaves, or cause them to grow out at right angles from

the stalk, rendering them more liable to be broken off. It is a good plan to have a piece of corn on the north side of a piece of tobacco, or, at least, two or three rows, to shield the growing plants from winds.

CUTTING AND HANGING.—The plants grow rapidly and require less than three months from the time of setting, before they are ready to cut. Any one used to the cultivation of the crop knows when it is ripe; the veins of the leaves are swollen, the leaves begin to look spotted, and feel thick and gummy. The ends of the leaves will crack on being doubled up. After it is ripe, the sooner it is cut the better, as it is liable to injury by frost or hail, and will not increase in weight as fast as the worms eat it, and the leaves get broken in catching worms. The plants will generally ripen from the first to the fifteenth of September: they should not be cut immediately after a heavy rain unless in danger of frost, as a portion of the gum washes out, but should be allowed to stand two or three days. The cutting should not begin until the dew is off; a cloudy day is best, for when the sun shines hot, they will not have time to wilt sufficiently before they will sunburn, which may be known by the leaves turning white and looking puckered. Commence on one side of the piece, laying the plants all one way, in order to facilitate loading. Most of the plants may be broken off easily, by gently bending them over one way and another. Small plants, which will not break, may be sawed off with an old saw or cut with a hatchet. If the sun shines too hot, the plants should be turned over carefully to prevent burning. After lying an hour or two, to wilt sufficiently, so as not to break by handling, they may be carted to the barn or shed. Ample room for curing should be provided, and if any one expects to raise tobacco for any length of time, it is best to have a building erected expressly for it.

BUILDINGS.—In the first place one wants to know about how much room he will need, and then build accordingly. To hang an acre of good tobacco requires a building about thirty by twenty-four feet, with fifteen-foot posts. Two girds should be framed into the posts on all sides of the building; one five feet above the sill, and the other ten feet above, to rest the poles on, also to nail the covering boards to. This gives a space of five feet for each tier of plants. Have a beam run across the center of the building, with a post in the middle with girds to correspond with those on the side, extending lengthwise through the middle of the building for the poles or rails, each twelve feet in length, to be laid upon; or if sticks are to be used (as hereafter described) lay rails or poles once in four feet for the sticks to rest upon. Place a ventilator upon the center of the roof, and have one board in every four feet hung on hinges, to be opened or closed at pleasure. If made with a floor and a cellar underneath, to let down the tobacco into when ready to strip, all the better.—We will now return to the crop, and commence hanging it. A common way of doing it is by tying with common twine. Tie the end of the string tightly around the but of one plant, and by placing it against the side of the pole nearest you, put another plant on the opposite side and carry the string over and around it, placing the plants alternately on each side of the pole until filled, then fasten the string, place the pole in the right place, (it should be nearly right before it is filled,) and commence on the next one in like manner, having some one to hand the plants as wanted. As to how thick to hang, it depends upon the size of the plants, but in good-sized tobacco about nine inches on each side is close enough; that will be from thirty to thirty-two on each pole of twelve feet; place the poles from fifteen to eighteen inches apart. Another method of hanging, much practiced and approved by many, is to hang on staks or sticks sawed out four feet long, one and a quarter inches wide and five eighths of an inch thick. Chesnut timber is generally used here. The common lab answers very well. An iron needle made something like a chisel is used to slip on to one end of the sticks, which are sharpened a little at one end to receive it. It is made about eight inches long, wedge-shaped at the small end, and a socket one half by one inch to slip on to the sticks. When ready for use, have a place fixed near where you unload, to hold one of these sticks out at right angles from a post, and about four feet from the ground. Let the plants be handed you from the load and slip them on the stick, piercing the stalk about six inches from the but; put six or seven plants of medium size on each stick—more if smaller. As each stick is filled, it may be carried to its place in the barn. In getting them to the top of the barn they may be handed up with a pitchfork, lifting them by the middle of the sticks. These sticks should be about eight inches apart. I think a greater amount can be put into a given space by this method without danger of sweating, as it is more evenly distributed. The loose leaves that have been broken off while handling, may be cured by placing four or five together and securing to a small pole, in the same way as plants are hung with twine.

SAVING SEED.—Strip the leaves off from the seed-stalks, and tie up the stalks to a stake driven into the ground by

them, else they may be blown over. The seed should be gathered before hard frosts destroy its vitality; when fully ripe the pods or seed-vessels may be picked off and dried, then crush or roll them between the hands until the seeds are all out; the seeds may then be separated from the chaff by passing it through a fine sieve.

CURING.—After the crop is all housed, the building should be well ventilated by opening doors, and the boards on hinges, to secure a free circulation of air throughout the building. On rainy, damp, or very windy days, the building should be shut up as tightly as possible, and opened again on return of fair weather. After hanging several weeks, until the leaves are mostly dried, the building should be closed to prevent the dry leaves from being broken by the winds. It usually requires about twelve weeks to cure the plants thoroughly, that is, so that there is no more juice in the leaves or leaf-stems; it matters not if the main stalk is not dry, you need not expect it, and there will be green leaves that will not cure but freeze while green, and are worthless. It will then be ready for

STRIPPING.—This must be done only after a damp, rainy spell has softened the leaves, so that they may be handled without breaking; it may then be taken from the poles and stripped as fast as taken down, or it may be carried into a cellar and be piled in heaps to be stripped at leisure; care must be taken, however, not to let it remain too long in this condition, as the green stalks would soon heat and injure it. To strip a plant, hold it in the left hand by the but, and with the other pull off all the bottom leaves and drop them on the ground in a pile for "fillers," or the poorest quality; next, take off three or four more, or until you come to the best leaves, these put in another heap for the "seconds;" now strip off the remainder for wrappers, except such as are badly worm-eaten or otherwise injured—such go into a poorer quality; throw the stalk away and put the handful of wrappers under the left arm to hold while stripping another plant in like manner, put the two handfuls of wrappers together, taking pains to keep the butts even, and bind them by firmly winding a leaf around them at the but, commencing within a half or three quarters of an inch from the end, and winding down smoothly about two inches, part the "hand" and put the end of the band between the parts, then close it again, thus securing the end and holding it tight. If the plants are very large, the leaves from each may be tied up separately instead of putting two together. Hands that will weigh half a pound are about large enough. The seconds and fillers are afterward picked up and tied in the same manner. Much of the value of tobacco in market depends upon the manner in which it is assorted and done up, as a few poor leaves in a hand would make a difference of several cents per pound in the price. None but good sound leaves, free from rust, pole-sweat, frost, or large holes should go into the best quality. Small plants rarely contain any first quality, but should go into the seconds and fillers. A little practice will enable any one to sort it properly, better than any rules that can be laid down on paper. There is much difference in the color and fineness of the leaf, a darkish red or cinnamon color is preferred to that of a darker shade; the veins should be small and far apart, and dark as the leaf, as "white stems" are objectionable by reason of their growing lighter still when going through the sweat after it is cased. After it is stripped, it should be packed down in a cool dry place. Lay some boards flat on the ground about four feet wide, and as long as you wish the pile to be, and commence by laying a row on one side of the platform with the butts out, then on the other side in the same way, letting the tips lap about six inches, or just enough to keep the pile level: proceed in this way, laying on each side alternately until all is packed. Lay the hands as close to each other as possible, not sprawled out like an open fan, but compactly. Lay some boards on top of the pile, and put on just weight enough to keep them snug. Some boards or blankets should be put at the ends of the pile to keep it from drying up. The seconds and fillers are packed in the same way; they may be packed in a separate pile or on top, or at the ends of the wrappers. It is now ready for market. If it should remain long in pile it should be examined occasionally to see that it does not hurt, as it sometimes happens that when taken down, stripped and packed when it is too damp, it will grow damper and perhaps rot. If too damp, it should be repacked on some windy day to give it an airing, shaking out the dampest hands and letting them remain exposed until sufficiently dry to be repacked. The stalks, after being stripped, should either be spread on grass land and remain until Spring, when they may be raked up and carted on to the land designed for the next crop of tobacco, and burnt, or let them remain in the barn until Spring, when they may be cut up fine and dropped into potato or corn-hills, using a good-sized handful to each hill.

I have raised the past season on a little more than three fourths of an acre, 1,427 pounds wrappers, worth at the present time 25 cents per lb.; 221 pounds seconds, worth 12 cents; and 146 pounds fillers, worth 10 cents; amounting to 1,794 pounds, worth \$397.87.

A. H.

Fig. 1.—POISON IVY.

Talks About Weeds....IV.

POISONOUS PLANTS.

We devote the chapter this month mainly to an account of a plant, which though it does not infest crops, is very common along old walls, and in neglected corners, and is of such a dangerous character that every one should be able to identify it. "Poison Ivy," or as it is sometimes called, Poison Oak, and Poison vine, is botanically known as *Rhus Toxicodendron*. It is a plant that presents several forms; sometimes it is a small shrub 1 to 3 feet high—sometimes it trails over stone walls and rocks, and again it is found climbing to a great height upon trees, to which it clings by means of numerous small roots that it throws out from its stem. All these forms are varieties of one species. The leaves are *three parted*, the divisions rather irregular in shape, and are either entire on the margins, or irregularly lobed or toothed. The flowers are in panicles, small and of a greenish white color, and are followed by whitish berries. The popular names given above, as well as the specific name *Toxicodendron* (Poison-tree), indicate that its reputation as a dangerous plant is well established. Touching or handling the plant will, with many persons, produce serious consequences; others, perhaps the majority, are not affected by it, while some are so very susceptible that by merely passing near the

Fig. 2.—VIRGINIA CREEPER.

plant, especially in hot sunshine, they will receive its poisonous influence. It is probably the

case that very few persons are capable of being poisoned by it. If it were otherwise, the plant being so very common, we should hear of more frequent cases of poisoning. Where a person is but slightly affected by the poison, there is a redness and violent itching of the face and hands, followed by little watery blisters. Where the effect is severe, the swelling and other symptoms are much increased. We have seen a person with the face swollen to such a degree that scarcely a feature could be distinguished. The usual treatment in poisoning of this kind is to give a cooling purgative, such as salts, and apply a solution of sugar of lead to allay the intense burning and itching. Unless in unusually severe cases, the effects do not last more than a week. There is a very harmless climber which is sometimes mistaken for the Poison Ivy, and avoided as being poisonous,—the Virginia Creeper. As the last is not only a perfectly harmless plant, but one of

our most valuable ornamental climbers, we introduce an engraving of a leaf of it, in order that the difference between the two plants may be readily seen. In the Virginia Creeper the

A. H.

Fig. 3.—POISON SUMACH.

leaf is *five parted* and much more thick and glossy. We have known one instance in which the Poison Ivy was used as an ornamental vine, it being mistaken for the Virginia Creeper; a rather unsafe plant to have near the house.

Another shrub of the same genus, *Rhus venenata*, called Poison Sumach and sometimes Poison Dogwood, is abundant in swamps and low grounds throughout the Northern States. It is a very pretty shrub or small tree, and with its pinnate leaves it looks somewhat like the Ailanthus. It is distinguished from our other shrubby Sumachs by its loose clusters of white berries. This is even more dangerous than the Poison Ivy. The above figures are taken from American Weeds and Useful Plants, a work which we have already highly commended.

TREE ROOTS IN THE TILE DRAINS.—One of the most important drains on the writer's premises had been so obstructed for several years by the fibrous roots of an elm, as to require it to be relaid twice in five years.

The last time, however, a new method was tried, and thus far (for four years,) the stream has run freely. The method was this: All along the line penetrated by the roots, the tiles were imbedded in water-lime mortar, then covered with a foot of tan-bark, and the remainder of the trench filled with common soil. The mortar soon becomes hard like stone, and the tan-bark both seems to keep away frost and the tree roots. [If tan-bark will repel the roots of trees, the lime would not seem necessary.—Ed.]

Hints about Farm Laborers.

One of the sorest troubles in farming, just now, arises from the scarcity of help,—a scarcity which must continue as long as the war lasts, unless an unusual foreign immigration supplies the want. Were it not for labor-saving machinery, multitudes of crops would go unharvested, and other farm work go unperformed. Along with this scarcity, the quality of the workmen left is also poor. Not all, indeed, but many of our hired men are eye-servants, working lustily while watched, but lounging, dawdling, and, perhaps, drinking when alone. Tools are not taken care of, the work done is slurred over, the horses and cattle are neglected, many

things are wasted—in short, the real interests of the farmer are not cared for. It is vexatious to try to carry on a farm with such "help." One must be always present with his men, must work hard himself, and do the worst jobs with his own hands. A slave's life is it to be bound to such a task, and the money gained by it, is earned at hard rate.—But here are a few helping thoughts. If a farmer can contrive to get young men into his employ, and can manage to keep them for a few years, he can train them into good workmen. Yet much depends on the employer himself. Many of our bad laborers have been made such by the unkindness, dishonesty, or shiftlessness of their masters. If a good farmer can get

young, unspoiled men, fresh from the "old country," and can keep them long enough to teach and train them, he will generally have good and faithful workmen. Hence, one way to improve our farm laborers would be for the agriculturists of a neighborhood to employ some trustworthy agent—say at New-York or Boston, to select companies of likely young foreigners who prefer country life, and then to send them directly on to the farmers wanting them. Also, let the farmers of each neighborhood pledge themselves not to hire a laborer coming from another farmer unless he brings a certificate of honorable discharge from his last employer. If the Agricultural Societies of town and county would form some system of this kind to provide a steady supply of good material for workmen, it would raise the character of our laborers, and relieve farming of one of its greatest troubles. Of course, it is implied that the farmer is to pay good wages, to study the wants of his men carefully, and to seek, in every reasonable way, to promote their comfort and happi-

Our Western Jaunt.

It is our aim to devote the mid-summer season of every alternate year, to a tour of observation through the western or mid-western division of the great *Agriculturist* Parish, which extends from the Atlantic to the Pacific. This year we went on our fifth western trip, out through New-Jersey, Pennsylvania, Central Ohio, and Indiana, into Illinois and Iowa, and returned through Michigan, Northern Ohio, and New-York, making occasional stops, going and returning. (In these trips we generally ride only in the day time, and usually arrange to secure a position in the center of the baggage cars of the railway trains, because the wide doors give an unobstructed view of the country on either side, and we there have the company of local employees of the roads, who are able to point out objects of interest, and to give much general information. In this way we see much of the face of the country, the style of culture, the condition of the crops, etc. Indeed, were we not to stop at all, but travel thus for 3000 to 5000 miles, we should consider the time well spent.)—Our main object, this year, was to study prairie farming, especially in Illinois and Iowa, which are *par excellence* the prairie States. We stopped at some twenty to twenty-five localities, and from observation, and conversation with practical men, gathered a large amount of information. It would be impossible to give a minute journal of what we saw, heard, and learned—as some may expect—a large volume would be needed. Sundry items will appear in this and other numbers, and we hope our western readers will find us still better prepared to supply a journal specially adapted to their wants, so far as there is any specific difference in the modes of cultivation East and West.

Beet Sugar—Important Experiments.

Much has been said and written upon the question of making sugar from beets, in this country. Many journals have urged the culture of the Sugar Beet here, claiming that it must be extremely profitable, because it has paid well in Europe, where the manufactured product is subjected to a high tax. We have been censured for refusing to admit into the columns of the *American Agriculturist* essays from those who are enthusiastic on the topic. The ground we have taken, has been, that there have not been sufficient experiments to demonstrate the practicability of manufacturing beet sugar to compete with the cheaper grown cane sugars of the Southern States and West Indies. That sugar can be made from beets in our climate, has been proved by experiments on a limited scale, with imperfect apparatus, but it is still a question whether the soil, climate, and system of labor in the Northern States, will enable us to practice the European methods with success. We are happy to chronicle the fact that at one point, at least, experiments on a large scale, with the best apparatus, are being carried on the present year. Last month we made a trip of a hundred miles out of our course, to see the establishment referred to, at Chatsworth, Illinois, a new town on the Logansport, Peoria, and Burlington Railroad, some fifteen miles west of Gilman Station on the Illinois Central Railroad. At this point (Chatsworth), Messrs. Gennert Brothers, (of 142 Center-st., N. Y. City,) have platted between one and two hundred acres of Sugar Beet, and are putting up a large complete building, with steam engines, evaporators, and other ap-

paratus, of the most improved and expensive character to be found in Europe. The Manufactory is in such a state of forwardness that it will be ready for the growing crop. We regard this as one of the most important agricultural enterprises of the day, and too much credit can not be given to the Messrs. Gennert, for taking hold of the subject in the way they have. It is wholly an experiment, and if successful will be of immense benefit to the whole country, for the manufacture of beet sugar will at once be gone into generally; while if it prove a failure, they and they alone will bear the loss, which must amount to forty or fifty thousand dollars at least. We made our visit unsolicited, and unexpectedly to the proprietors, and we found them rather disposed to keep the matter quiet, but we think the country should know what is being done, and that the Brothers Gennert should have the credit of the enterprise, which will be equally creditable to them, whether a success or a failure. We wish them the largest success and profit in the undertaking. Until we have the result, it is not important to describe particularly, either the manufactory, or the process of growing and manufacturing the roots. If successful, we shall take the earliest opportunity of placing the whole matter before our readers.—At the time of our visit (July 24,) the long continued drouth was likely to greatly injure the growing beets, and it was feared that another week of such weather would destroy them for the season. As a heavy rain came on before we were twenty minutes away, we trust the feared calamity was averted.

Sorghum.

A BIT OF HISTORY.

Seven years ago (1856) we raised our first plot of Sorghum, or "New Chinese Sugar Cane," as it was popularly called. We published an account of it, describing it as promising well, and recommending our readers to try a little garden plot, to see how and where it would grow, and offered *free* to our readers all the seed we had grown and could procure—a little parcel to each—but cautioned all against going into its culture extensively, even if seed could be procured, until its merits and demerits were better known. Shortly after, a stranger called and offered us *half a dollar an ounce* for all the seed we had, which was refused as it had been promised to our readers. On further inquiry we gleaned from him that there was such a rage for the seed at the West, that he could divide an ounce into a dozen parcels and sell them at \$1 each. We immediately set about procuring, direct and indirect, all the seed we could obtain in France and Algeria, where alone it had been cultivated to a moderate degree. Several lots, of 100 to 300 lbs., were secured, and we commenced scattering it *free* among our readers all over the country. *Six thousand* parcels were sent to Illinois alone. Some of our cotemporaries cried out "humbug." But as we then answered, where was the humbug when we gave away all the seed, and specially advised our readers to try it only on a small scale?—The seed thus sent out was grown and propagated by twenty to twenty-five thousand persons; and it is not claiming anything too much to assert that three-fourths, if not seven-eighths, of all the sorghum now grown in this country has come from the seed thus sent out *free* from the Office of the *American Agriculturist*. Of the advantage to the country, let the tens of millions of gallons of good syrup produced last year, and to be produced this year, bear witness.

SORGHUM GROWING IN IOWA.

During our recent visit in Iowa, we found that a large proportion of the families in that State depended mainly upon home-produced sorghum syrup for family sweetening. A little sugar is used for tea, but even tea, and especially coffee, is frequently sweetened with syrup, owing to the scarcity and high price of sugar. The sorghum syrup is a common article of sale at the stores. We saw sorghum mills, generally home-made with wooden rollers, in almost every part of Iowa visited, and very frequently in Illinois. In Iowa, there will, perhaps, be not much more grown this year than last; the opinion seemed to be that it would pay to grow enough for home use, but not to produce it for export, except when done on a large scale with improved apparatus. We saw hundreds of small plots, of $\frac{1}{2}$ to $1\frac{1}{2}$ acres, and occasionally a large field. The growth and manufacture of sorghum on a large scale is in progress in several localities in Illinois and Ohio, and somewhat in Indiana.

400 ACRES OF SORGHUM.

Near Utica, Illinois, on the Chicago and Rock Island Railroad, we saw a plot of about 400 acres of sorghum, which is being grown for special experiments, by Mr. Belcher, the great sugar refiner of Chicago. We called upon Mr. B. in Chicago, and learned from him that he intends to boil down the juice to syrup, and then transport it to his Refinery in the city, and operate further upon it. After learning his plans and views we concluded that his experiments will be of special value to the public, and perhaps result in settling the question whether good grained sugar can be profitably produced from sorghum. Mr. Belcher has refined many thousands of gallons of the syrup during a year or two past, and has contracted for a large amount this year. He promised to give us the results of this year's operations, especially in his experiments with the 400 acre plot. In this line, he is doing for the public what the Brothers Gennert are, in the matter of Beet Sugar.

For the *American Agriculturist*.

The Autumn Exhibitions.

The time is just at hand for our great annual agricultural shows. We hail their return—not because we think them unmixxed with evils, or beyond improvement, but because of the many good influences attending them. Their social influence is not to be undervalued. They bring together old friends, and lead to the forming of new acquaintances; they call out all classes and ages from different communities, and bring them together on terms of equality and good feeling. We, hard-working, care-worn Americans, give none too much time to such social gatherings. And then they appeal happily to the public taste. One can hardly spend a day more profitably and enjoyably than by attending a well-conducted Fair. It would be strange if he did not see or hear something new. No gardener possesses all knowledge respecting vegetables, fruits and flowers. No one farmer knows all possible things concerning stock, grains, grasses, farm implements, and the numerous processes of husbandry. Then, too, the ingenuity of the ladies is always bringing out some new display of handy-work which attracts large admiration. And, beside these, there are numerous articles of the fancy sort, which please and instruct beholders. We are not altogether inexperienced in Fairs, yet we never attend one without learning something new. And we always see young

and uninformed persons fairly filled with surprise at what they behold. Many a gardener, wise in his own conceit, has had his eyes opened to the difference between poor vegetables, apples, pears, plums, cherries, etc., and good ones. Many a man, who had thought the Fox grape the best of all grapes, or at least good enough, has got a new idea or two on tasting the Delaware, Diana, etc. And these men go home with new impulses, resolved to adopt and realize their new ideas in their own practice.

There is, however, room for improvement in our Fairs. Would it not be well to discourage more and more the accompanying shows of three-legged calves, double-headed sheep, learned bears and monkeys, and manifold monstrosities and humbugs? Female equestrianism is no proper part of an agricultural exhibition. Might not some further means be used to convey useful information to those seeking it? If fine-looking fruit garnishes the tables, why not let us know something of its quality? And if any one wishes, why not let him know something as to the mode of pruning and training, the fertilizers used, etc., etc.? Perhaps an afternoon or evening might be set apart for answering all such questions and giving other information. This would send the people home instructed and pleased. The practice sometimes adopted of devoting an evening to *discussion* of practical topics, is highly commendable. We should have some simple plan for communicating information to the uninformed. The practice of awarding premiums for the best-managed farm or garden, or fruit orchard, for the best written essays on practical topics, for the best new seedling of any fruit, are all movements in the right direction, and might well be adopted by all such societies. RURALIST.

Various Humbugs.

It is a thankless task to fight humbug in its various phases. No sooner is it killed in one form, than it rises in another guise more specious than before.—One theory which quack doctors most make use of, is, that all diseases arise from impurity of the blood—if we can only purify the blood, all diseases will disappear. This is beautiful in theory, and takes readily with the ignorant and easily gullible. The only objection to it is, that it has not the least foundation in fact. If any man, whether calling himself a physician or not, talks about *purifying the blood*, it is safe to set him down as a humbug of the rankest kind. Some weeks ago we saw a long article in the N. Y. Tribune, recommending the root of *Veronica quinquefolia*, as a grand panacea for scrofula in all its forms. We felt grieved to see such a quackish article in so widely circulated a paper, but let it pass unnoticed. Now that we see in our esteemed contemporary, the Rural New-Yorker, another article by the author of the one which appeared in the Tribune, we feel called upon to expose the thing. On reading these articles we, of course, suspected that there was a cat hidden under the meal, and upon making an inquiry, we ascertained that the writer of the articles was selling the root at three dollars an ounce, or two ounces for five dollars. The price of the article in the New-York drug and herb stores, is less than one dollar a pound! The editors of the Tribune and Rural New-Yorker, have unwittingly allowed the use of their columns to aid a private and extortionate speculation. It is a sort of spasmodic revival of an old thing which has been before the public in one way or another

for the past 20 years. The medicine in question is the root of a plant, the proper botanical name of which is *Veronica Virginica*, and has been called *Leptandra Virginica*, and *Veronica quinquefolia*. The common name is Culver's Root, and it is sometimes called Indian physic. Though not very common around New-York, it is abundant enough through the West.

In regard to the medicinal qualities of the plant, we have only to say, that it is much used by the so-called "herb doctors," and it possesses powerful cathartic and emetic properties. We judge it to be altogether too active an agent to be used unadvisedly. If one is ill enough to require a medicine of this kind, he is in a condition to need the advice of an intelligent physician. We are decidedly opposed to indiscriminate dosing, hence we exclude from our columns all advertisements of patent or quack medicines, although people who have these to sell, can, from the large profit they make, afford to offer very high prices for advertisements.

We find by an occasional advertisement in some journals published at distant points that

"Dr. James, a well-known retired physician, discovered, while in India, a sure remedy for Consumption, Bronchitis, Colds, etc. To help suffering humanity the recipe will be sent for 2 stamps to pay expenses."

He may truthfully say he is well known. His plan of operations, and that of many others of his class, have been repeatedly exposed in these columns and elsewhere. Upon applying for the remedy you will receive a pamphlet recording marvelous cures, with the information that you can best procure the prepared remedy by forwarding a dollar or more to him, or his agents, and upon taking said remedy you will discover that both it and yourself have been sold, and that the advertiser has made all the profits. A correspondent inquires how such parties obtain the addresses of private individuals at distant points, to whom they mail their circulars, pamphlets, etc. In various ways. Sometimes by means of the postmasters; but usually from parties that make a business of collecting names by agents in the various towns. For a consideration, these parties will address circulars to any part of the country.

One of the most prevalent methods of swindling now in vogue, is seen in the following advertisement which with others of the same import, has recently appeared in some City papers.

"The undersigned will for one dollar send private instructions to any party, how he may escape the draft without risk, at a cost of only 37 cents."

From appearances, this advertiser will reap quite a harvest from the cowardly renegades who are willing to enjoy the benefits of a good government, and are unwilling to give their services for its maintenance. Perhaps it is as well to allow such to send their dollar and find that their pusillanimity costs more than courage would do. We have little sympathy for them, but we are not willing that scoundrels should fatten even at their expense, and therefore give notice that any party advertising that he can give exemption from military liability by any device, by false certificate of physical weakness or otherwise, is a swindler. We would also hint to the said advertisers, that the Provost Marshal is on the track of some of them, and that they are liable to a draft which will entail harder service than even the military are usually called upon to perform. The penalty for interfering with, or in any way discouraging the procurement of men for the army, is, as it should be, proportioned to the enormity of the offence.

There are a few distinguishing marks by which one may, with great certainty, distinguish

between legitimate advertisements of *bona fide* concerns, and the schemes of plundering swindlers. When a "secret" of any kind is advertised, look out for humbug. Honest men are willing at the first to make known the nature of the articles they offer for sale. The old adage "Never buy a pig in a bag," applies with peculiar force to such cases. Advertisements that promise more than a dollar's worth for a dollar, that offer to ensure a fortune or a good living with little or no capital, and without much labor, are traps for the unwary. Finally the whole class of advertising physicians who perform wondrous cures on paper, are men who seek to gain a living by duping the credulous.

For the American Agriculturist.

Country Cemeteries—Good Hints.

Some time ago I was riding to a village in one of the Western States, and had my attention called to the cemetery just outside the village, by the exclamation: "That's where they plant 'em." Indeed, from the cemetery and its surroundings, the remark did not shock me. A desolate, sandy knoll had been chosen as the last resting place of those who had lived in the village. Its scanty growth was cut off, and the stumps stood more numerous than the grave stones; and to crown all, it was surrounded by a wooden fence, painted bright red. "That's where they plant those whom they expect to bloom in immortality," said I to myself. My mind wandered to the quiet beauty of Mount Auburn, Swan Point, and Laurel Hill, and to the charming and commanding views of Greenwood, and I thought that we of the cities "planted" our dead in more attractive spots. Having travelled largely through the country, I have been exceedingly pained at the general desolateness of the village cemeteries. Why is it not just as easy to choose for them a pleasant place, as a cheerless one? It is a melancholy satisfaction to most of us, to visit the last resting place of those who were dear to us in life, and, though it will make little difference to those who lie there, it is vastly to the comfort of surviving friends that they can go to a pleasant and attractive place to see all that earth has left of those dear to them. To sensitive minds it is a horrible thought that their bodies shall be laid in the bleak cold grave-yard; if they could know that they should be buried in the shade of trees, and that flowers would bloom around and birds sing above their graves, death would lose many of its terrors. I am far from justifying this feeling, but we know that it exists to a great extent. I would, through the widely circulated *Agriculturist*, call upon the influential men in every town and village, to see that their cemetery is made an attractive place—one where the living can cheerfully hold silent communion with the departed, a place which will show to strangers that the dead are not merely "planted." A few people of taste and energy can in any community effect a reform in this matter. The most beautiful cemetery that I know of owes its existence to my old schoolmaster. There is one thing which I would have changed in all cemeteries; that is the placing of fences around private lots. It breaks up the general design, and gives a formal and gloomy aspect which should be avoided. Death levels all distinctions, and if it is necessary to designate between mine and thine, even in the grave-yard, it can be done by small corner stones which will not intrude themselves unpleasantly upon the visitor. T. G.

WEeping BEECH—AT FLUSHING, N. Y.

Sketched and Engraved for the American Agriculturist.

The Ornamental Varieties of the Beech.

The European and our native Beech are so nearly alike, that some botanists have considered them as the same species. There is a slight difference in the shape of the buds and leaves, but they so much resemble one another in form and habit, that for the purposes of planting as shade trees, they may be considered as identical. We have often wondered why the beech was so much neglected in tree planting. It may not have the grace of some other trees, but for affording a perfect shade, no tree is equal to it. Another thing which commends it, is its cleanliness and general freedom from the attacks of insects; and besides, its foliage remains in Autumn much

Fig. 2.—CUT-LEAVED BEECH.

later than that of other deciduous trees. Many of our readers will recollect some particular beech tree whose cool shade was a favorite retreat in their boyhood, and where enjoying the shelter that it afforded, they whiled away the sultry hours of a summer's afternoon in carving some favorite name upon the bark, which offers a tempting surface to the knife. The European Beech has made several accidental sports which have been propagated by grafting, and are now very generally distributed. One of the oldest of these is the purple beech, the original tree of which

was discovered in Germany in the last century. The young leaves are of a cherry red, but as they grow older, they become darker, and eventually are of so deep a purple as to give the tree, among the French, the name of black beech. The purple beech in Spring is a very attractive object; the young leaves when agitated by the wind, during bright sunshine, make such a brilliant show as to give the tree the appearance of being on fire. The seeds of the purple beech have produced many colored varieties; the best known of these is the Copper beech, which has lighter colored foliage than its parent. Both these sorts are desirable in a collection of ornamental trees.

Another and very interesting variety of the beech is the cut-leaved or the fern-leaved, in which the foliage is variously divided and in some forms even shredded. Figure 2 shows one form, but there are others in which the divisions are much finer. This is a most graceful foliage, and the tree is worthy of being planted much more frequently than it is. Mr. Sargent, the well-known writer on landscape gardening, says, if he could have but six ornamental trees, the fern-leaved beech would be among the first he would choose.—Many forest trees have produced seedlings, the branches of which have a drooping or pendulous form; these are commonly called "weeping" trees, and we have weeping varieties of the elm, ash, birch, beech, and many other trees. None of these weeping trees are more beautiful than a well grown *Weeping Beech*. The original tree was found in the grounds of an English Park, and it has been propagated by grafting, and is now not very rare in this country, though not nearly as well-known as it should be. The finest specimen within our knowledge is in the grounds of Messrs. Parsons & Co., at Flushing, N. Y. With the hope of bringing this most graceful tree to the notice of those about to plant for ornament, we have had the specimen drawn

and engraved. [The artist sent specially to make the sketch for us, has failed to represent the real beauty of the tree; it has a heavy, thick, dark foliage, and every branch and leaf should have been represented as pendulous—hanging almost perpendicularly downward—the upper branches less spreading, and turning in a short curve, and the lower ones thickly massed, and gracefully drooping their ends to the earth.] Always attractive, it is toward sunset that this tree shows its beauty most strikingly; then the pendulous branches throw deep shadows, and the whole tree is a picture of light and shade worthy of the study of an artist. For small places and for situations near the house, no tree presents more desirable qualities than the weeping beech.

Tall Trees—The Douglass Fir.

Many of our readers will remember an account published in the *Agriculturist* some time since, of an enormous flagstaff sent to England from Oregon. The gentleman who presented it gives the following interesting particulars concerning the growth of trees in that State, which we find in the London Agr. Gazette:

"Douglas Fir, better known in this part of the world as Oregon Yellow Pine, is generally from 200 to 300 feet high, frequently 150 to the first branch; has a corrugated bark on a full-grown tree, 6 or 7 inches thick; sapwood, 2 to 3 inches thick; roots spread over a large extent of ground, but no tap root, or root growing from the center downward. The largest tree that I have had cut, was one measuring 9 feet at the but, including the bark, and 306 feet from the but to the top; it squared, clear of sap, at 45 feet from but, 40 inches; it was cut at 136 feet, this being the proportion of length to diameter of a mast, for which purpose I sent it to England in 1858. One great advantage the Douglas Pine (generally so called in England), has over all other trees, is the very little taper I have seen trees in which at first you could not tell the top from the butt—I mean trees cut for masts of 100 to 130 feet long. For all purposes this is an advantage, inasmuch as the tree contains more timber, but for ship masts this is an invaluable quality. I have recently built a vessel of 200 tons, and no other timber but Douglas Pine was used in her construction.

"Spruce is plentiful, but less abundant than Douglas Pine; it is closer grained, and, I think, better timber than the same wood of Canada; grows to about 200 feet high, and fully as great diameter as the Douglas Pine; the roots furnish knees for ship-building purposes, which I consider equal to Oak.

"Hemlock is not held in much repute here. I have only seen it used for wharf piles. It is plentiful and grows to a height of 150 to 200 feet.

"White Pine is very scarce here, consequently very valuable, as it is almost the only wood we have fit for joiners' fine purposes. It grows about 200 feet high; 40 inches is a large tree.

"Red Cedar has generally a short trunk, with large spreading branches. When it can be found clear of knots, it is as valuable as White Pine. The Indians make their canoes from this tree, hollowing it out; many of them convey 50 to 60 men, and the most perfect models of the clipper I have seen. I consider the Cedar the most ornamental tree I have met with. It is generally found near the water, or, I should rather say, grows larger near the water, and on swampy ground; but I have found it in the interior of this island, near the lakes on the side of the ris-

ing ground. Here it grows tall like the White Pine, and seldom exceeds 30 inches in diameter, 60 to 80 feet clear of knots, and not hollow, as generally is the larger short-trunked tree of the same name."

Half Hardy Trees and Shrubs.

Were we to speak our whole mind on the subject, we should confess that we grow more and more inclined to discard the tender things, and to plant only such as are as tough as oaks or burdocks. Yet, on the whole, we must say, not so; for if we did, we should exclude many very fine trees and plants, and lose much of the *variety* which now gives our grounds a great charm. How, then, to manage them well?

The notion prevails with many, that such vegetation should be planted in sheltered spots, (say on the south side of buildings, high fences, etc.) and in rich soils. But this is a great mistake. When so planted, the wood is stimulated into a rapid and a late growth, which can not ripen up hard and dry before the Winter sets in. The consequence is that this soft, sappy wood is frozen to death. Rather, choose an open, breezy aspect, exposed to the North and West.

The soil should not, indeed, be so barren that the tree or bush will be kept in a feeble, half-starved condition. If so, the Winter will destroy it, of course. Nor should it be deep and rich, for this will induce too rampant a growth. Let it be of moderate fertility, and dry, rather than wet. And, as we would not choose the top of a bleak hill, so we would avoid a low, moist valley. By a little considerate management of this sort, we shall be likely to get a moderate and healthy growth of plump, short-jointed limbs, which will be quite sure to ripen off well before hard frost.

If, on the setting in of December, we can give our half-hardies a little protection on every side, using, perhaps, a few evergreen boughs, it will be a good thing. Drive stakes on every side firmly into the ground, and then tie the boughs to these. This will make a nice little local climate, for which the pet will thank you. A friend of ours in central New-York succeeds well with the *Rhododendron Catawbiensis*, by planting a circle of white pines (any evergreen would do just as well) and setting his plants in groups in the centre. This screens them alike from sun and cold winds. Without some such screen, they are likely to suffer there.

Our Neglected Native Forest Trees.

An experienced and observing botanist once made the remark in our presence, that there was not a single American tree in any park or public square in the City of New-York. Since the creation of the Central Park, this remark does not hold true, but it expresses the fact as respects all the other parks in New-York, and may be extended to apply to most of the private grounds within our knowledge. In planting trees we have run too much after those of foreign origin, to the neglect of American trees. While we will not deny that many of our imported species are every way desirable, we at the same time maintain that we have those of American origin which are equally as good. Our people who plant trees, only know that they want rapidly growing ones, which will make a shade as soon as possible, hence they generally state the number of trees they require, and leave the selection to the nurseryman, who, naturally

enough, supplies those which cost him the least trouble to produce, and of which he has an abundant stock. In this way only can we account for the constant sameness in the kinds of trees, whether in our streets, public parks, or private grounds. Our American trees are highly prized in Europe: we have a friend who annually sends hundreds of pounds of the seeds of our common trees to the nurseries of France. The seeds of our native trees are generally much more difficult to find in commerce than are those of European trees, and this may be another reason why our nurserymen raise so much more foreign stock. Some try our native forest trees by taking seedlings from the woods and transplanting them to their grounds. This method is sometimes successful, but more frequently fails. The one making the attempt is disgusted

LEAF OF LIQUIDAMBAR.

at the failure, and sends to the nursery for foreign trees, which grow well, and he comes to the conclusion that wild trees can not be cultivated. Now if the American trees had been grown from the seed and treated in the same way as the exotic ones, i.e., transplanted several times, he would have had no difficulty. Herein consists the main difference between trees taken from the woods, and those from the nursery. In one case they have some large main roots and few fibrous ones, while in the other case, the trees have been transplanted several times and have thrown out numerous small roots. In one case the removal is a great shock to the tree, and in the other, it is prepared for, and is but little affected by it. Most persons would be astonished to see how few years it takes to raise a good sized forest tree from the seed. Those who have large places should always have a small nursery of forest trees from which to draw as the occasion may demand. Seeds may either be planted as soon as they fall, or be kept through the winter in boxes of earth, and then sown. The seedlings generally need a partial shading during the first year of their growth, and after they have grown two years in the seed-bed, they may be transferred to nursery rows, and when they begin to crowd one another, they should be again transplanted to other rows. Treated in this way, most of our forest trees will form fibrous roots and may be used for planting with probability of success. Among the less cultivated of our native trees, and indeed but little known in the wild state, is the Sweet Gum, *Liquidambar styraciflua*. Downing, who had such a correct eye for the beautiful says: "We hardly know a more beautiful tree than the Liquidambar in every stage of its growth, and during every season of the

year. Its outline is not picturesque or graceful, but simply beautiful, more approaching that of the maple than any other; it is, therefore, a highly pleasing, round-headed or tapering tree, which unites and harmonizes well with almost any others in composition; but the chief beauty lies in the foliage. During the whole of the summer months it preserves, unsoiled, that dark glossy freshness which is so delightful to the eye; while the singular, regularly palmate form of the leaves, readily distinguishes it from the common trees of a plantation. But in Autumn it assumes its gayest livery, and is decked in colors almost too bright and vivid for foliage, forming one of the most brilliant objects of American scenery at that period of the year. The prevailing tint of the foliage is then a deep purplish red, unlike any symptom of decay, and quite as rich as is commonly seen in the darker blossoms of a Dutch parterre. This is sometimes varied by a shade deeper or lighter, and occasionally an orange tint is assumed. When planted in the neighborhood of our fine maples, ashes, and other trees remarkable for their autumnal coloring, the effect, in a warm, dry autumn, is almost magical. Whoever has travelled through what are called the pine barrens of New-Jersey in such a season, must have been struck with the gay tints of the numberless forest trees, which line the roads through those sandy plains, and with the conspicuous beauty of the Sweet gum, or Liquidambar." The bark of this tree when full grown, or nearly so, is exceedingly rough and furrowed, like the oak. The wood is fine-grained, and takes a good polish in cabinet work, though it is not so durable, nor so much esteemed for such purposes, as that of the Black walnut and some other native trees. The average height of full grown trees is about 35 or 40 feet. The engraving gives the peculiar form of the leaves. An abundance of seeds are produced, though but a small portion of them are perfect. It is readily raised from the seed, which may be had at the large seed stores, and trees suitable for planting may be procured at the nurseries.

Experience with Scale Lice.

O. F. Meyer, Rock Co., Wis., writes as follows: "In June *Agriculturist* you ask for information about the destruction of the bark-louse on apple trees, and here is my experiment and success. Two years ago I moved into my place, which I had formerly occupied and then let out. I had planted, when I first lived there, eight apple trees, one 15 years old, and some wild crab apples were on the ground, also a few plum trees. During the time I let the place out, everything was neglected; the weeds were almost as high as the young trees. My first work was to get rid of the weeds, and then I discovered that all the trees, wild and cultivated, were literally covered with the scale louse, and the same was the case with the currant bushes. My neighbors said, I could not do anything with the trees, but to cut them down, but I thought it worth trying to save them. In February I scraped the trunks and twigs of the trees as far as I could reach them; in April, I washed them with soft soap, ashes, and a little salt, which I applied pretty thoroughly with a brush. This I repeated in June, and pruned the wild apple trees at the same time. This Spring the same process was gone through with, and now one must look pretty sharp to discover a louse.

It is not strange that owners of orchards complain about this insect at the West. Most men

plant the trees and think that sufficient. I see here many a fine apple tree which would yield a handsome profit to the owner, if it were only treated right. There is no question that grapes and other fruit will grow finely at the West, if proper attention and care be given them."

A Horticultural Exhibition.

We would remind all growers of fruits, flowers, and vegetables, within reach of New-York City, that there will be an exhibition of horticultural products during the last week of the fair of the American Institute. The articles for the horticultural exhibition must be at the Academy of Music, 14th-street, before noon of Wednesday, Sept 16th. Liberal premiums are offered and we trust that there will be a general display. It is some years since we have had an exhibition that at all represented the horticultural capabilities of New-York and its neighborhood. We hope that our cultivators will this time appear not only as spectators, but as exhibitors. There are some things in the premium list which we would like to see altered. Thus low premiums are given for Quinces and Cranberries—fruits that need especial encouragement—nor do we think sufficient attention has been paid to garden vegetables. Squashes and Pumpkins, which are produced with comparative ease, have special premiums, while Cauliflower, Egg plant, Endive and other things, which require the best skill of the gardener, are not noticed in the prize list. We do not mention these things in a fault finding spirit, but as hints to be considered another year.

For the American Agriculturist.

New Lawns.

The soil should be made deep at the outset. If the land is poor, a coat of old manure should be turned under. This will prevent the drying up and burning out of the grasses in mid summer, as it will cause the roots to strike deep for nourishment, and will furnish them the food they need. After the plowing, harrow smooth, sow the seed, brush it in, and afterward roll it. Cultivators are not perfectly agreed as to the best grasses for lawns. Some advise the sowing of only one kind of seed; others favor several. In some of the finest bits of natural lawn which we have noticed by the road-side, we have counted several sorts. Kentucky Blue Grass is a favorite in some quarters; others prefer Red Top. In the writer's experience both have done well; the Red Top was mixed with a little sweet scented vernal grass and white clover.

It is a question with some whether the grass should be sowed by itself, or with some other crop, as oats, barley, or rye. For lawns of ordinary size, we would recommend to sow the grass by itself, and to sow liberally enough to cover the land at once with grass. It is also a question whether lawns should be mowed the first season. English cultivators say Yes. This practice may answer well for the British climate, but not so well for ours. We have seen many a new lawn injured by too early cutting. To stand well, grass needs time to form large, vigorous roots, and to strike them well into the earth, but this they can not do if the tops are cut off in mid-summer. All that is taken from the top is so much lost to the roots. In the second and following years, when the roots become strong and well established, the mowing may be frequent. The first year, we would

simply pull out weeds, and leave the grass to rot on the surface in Fall and Winter. *

[Our own preference is for one kind of grass, as this gives a uniform growth. After trying several kinds, successively, and in a mixture, we have settled upon the Kentucky Blue Grass as just the thing for our locality. It is perfectly hardy, and though starting slow the first season, it eventually makes a firm, compact, even, velvety sod, that will endure hard freezing even under water. We sow the seed very thickly to start with—at least 3 bushels to the acre.—Ed.]

The Yeddo Grape.

There has been so much interest felt in this grape and its introduction to this country has been so much desired, that a description of its habit and growth will doubtless interest our readers. The first account we have of it, is from the pen of Robert Fortune, the well known Chinese traveller, and was published in the Gardener's Chronicle for April 27, 1861. He says: "The vine of this district, which we may as well name at once the 'Yeddo Vine' produces a fruit of great excellence. The bunches are medium sized, the berries are of a brownish color, thin-skinned, and the flavor is all that can be desired. This grape may be valued in England, where they have so many fine kinds, and most certainly will be highly prized in the United States of America. A few years ago, I was travelling from Malta to Grand Cairo in company with Wm. C. Bryant, the celebrated American Poet, and a genuine lover of horticultural pursuits. This gentleman informed me that owing to some cause, our European vines did not succeed much on the other side of the Atlantic, and suggested the importance of introducing varieties from China, where the climate as regard extremes of heat and cold is much like that of the United States. I have never met with what I consider a really good variety of grape, and therefore have not been able to act on Mr. Bryant's suggestion. At last, however, we have a subject for the experiment, and I urged its importance on Dr. Hall, who is an American citizen, and who has already introduced a number of plants to his country from China. He enters warmly into the matter, and no doubt will accomplish the object in view. I therefore conclude this by giving notice to your readers to look out for the arrival of the 'Yeddo Vine.'"

The above is an account given by the celebrated Mr. Fortune, a perfectly disinterested witness. Knowing that Messrs. Parsons & Co., the well known nurserymen at Flushing, L. I., had received from Dr. Hall a specimen of this vine, we have requested them to give us their experience with it. They write as follows:

"We at once grafted it upon a strong native vine, and planted it in a good soil. During the last Winter it was covered with straw, and up to this time, its growth is very remarkable, and scarcely surpassed by any of the native sorts. The main stem is as thick as a man's finger and from it proceed four strong branches, seven and eight feet long. By Autumn they will probably be twelve or fifteen feet. The leaves resemble those of the Delaware, while the stem is unlike any other grape known. The vine will be left entirely exposed the coming winter—it was too small to be exposed the past winter. There is every reason to suppose it will be perfectly hardy, because nearly all the plants which have hitherto been introduced from Japan, have proved hardy in our climate. The interest now felt

everywhere in grape culture, gives additional importance to the introduction of this grape, and should it prove all we hope, Dr. Hall will have rendered a great service to his country."

Notes on Strawberries—Mulch them.

While in most locations the Triomphe de Gand sent out by us, has proved an abundant bearer, we occasionally hear complaints that but little fruit is produced. It would be strange if a strawberry of European origin should prove to be perfectly adapted to every locality throughout our extended country. Let any one look over the transactions of the American Pomological Society, and he will see that fruits, such as apples, pears, etc., which stand high in one region, are unsuccessful elsewhere, and are condemned for general culture. It is so with strawberries; their fruitfulness is affected by local influences, and it is only by experience that we certainly can know a variety will succeed in a particular place. Horticulture learns as much from failures as from successes. With the great number of fine sorts of strawberries we now have, there is no doubt that some good variety may be found which will succeed in each locality. With regard to the Triomphe de Gand, we believe it to be the best strawberry for general culture yet introduced. It may fail in some localities, but we have had nothing thus far that has proved so generally satisfactory. Some persons have made a point of the fact that it is condemned in Europe. True, but it is there rejected for the very qualities which render it desirable here. It is the only one of the European varieties which has attained a general success in this country. On the other hand our favorite kinds, originating here, have failed in Europe. With strawberries, we must judge as we would of other fruits, by their merits in our own particular region. We have sent out the Triomphe de Gand, as the most promising sort known, and have seen no reason to regret it. There may be failures and probably will be. Where it does not succeed, the person who really wishes strawberries, will try other sorts until he finds one which will do well with him. Many try a single kind and finding that will not grow, give up the cultivation altogether. If they would only communicate the fact of their failure, and give the public the result of their experience, they would do a good service to all in their vicinity. We hope to make strawberries as common in every family, and as much a matter of course, as potatoes, and we give from time to time such advice as our knowledge warrants. Let those who have facts, showing either success or failure, communicate them in order that their experience may benefit others. We commenced this article for the purpose of calling attention to mulching. There is very often a drouth just at the time that the strawberry is setting its fruit. In large beds it is impracticable to water them, and the only way to prevent the earth from drying is by mulching. In the Fall, after growth has ceased, cover the bed with straw. In the Spring when the plants start, uncover each crown, but leave the straw in its place. This will keep the ground moist during early drouths, and keep the fruit clean. After the berries are picked, the straw may be removed.

STRAWBERRY ITEM.—I. G. Hiler of Boston, Mass., in renewing his subscription for next year, to be sure of the "Agriculturist Strawberry," writes: "An article in your paper three

years since determined me to have a bed of strawberries. I immediately set a bed 30 feet long by 7 feet wide, with Early Virginia Scarlet (which I consider a humbug), Cutter's Seedling, and Bunce's Seedling, and kept them in rows, with no runners. I manure in early Spring, and after the crop is gathered, with Coe's Superphosphate. Last year I picked 50 quarts of berries, and the same this season, though the dry weather diminished my crop at least one half. I counted 180 berries on a single stool of the Bunce variety, and many other plants were equally loaded."

Starting Strawberries in Pots.

Strawberry plants, if well rooted in pots in July or August, may be put out in beds any time before the ground freezes and produce a fair crop the following season; the earlier they are put out, the better of course, as it gives a longer time for the plants to grow, and form large crowns, which will throw out a number of fruit stalks the next season. One advantage of setting out plants rooted in pots is, that they rarely ever fail to grow, and consequently need not to be replanted, which involves considerable time lost in the actual growth of the plant, besides the trouble of replanting, watering, etc. Another object gained is, that they rapidly advance in growth, and are not put back by transplanting, which is always the case with those planted in the ordinary way; nor are they so much affected by drouth. The greatest advantage is, that while those planted in the ordinary way produce little fruit the next season, except under very favorable circumstances, those in pots yield a fair crop, and more than repay the extra labor in the greater amount of fruit. Mr. C. S. Pell, of the N. Y. Orphan Asylum, starts strawberries in pots very successfully. He takes three inch pots, fills them with good soil, and places them in the strawberry bed—one under each joint on the runners—and small stones are put on to hold them in place. The earth in the pots is well watered and in about three weeks he has strong, well rooted plants, which may be turned out into the ground without checking the growth. If the pots are sunk in the soil of the bed, the earth will not dry out so fast and less water will be required. This plan offers many advantages to amateurs and cultivators on the small scale, or for home use.

Protect the Fall Flowers.

It is often trying to one's patience to have the frosts come and smite our splendid collections of flowers in the very height of their glory. In many cases, as with the Asters, Stocks, Balsams and Dahlias, we have watched and nursed them all Summer, and now, just as our care is beginning to be rewarded, suddenly, in a single night, the destroyer comes and blasts all our hopes! Last Fall, the writer tried an experiment to protect flowers several weeks, and succeeded so well that he is moved to speak about it. Just before frosts were expected, we provided a few light mats, made of sacking, and by driving down several stout stakes at the corners and middle of each bed, were enabled to suspend them over the flowers without crushing them.

Every observer must have noticed that we usually have a few sharp frosts early in Autumn, cutting down all tender things, and then that this is followed by several weeks of warm weather. Whatever plants go through the first frosts

unharmd, bloom finely for quite a period afterward. The use of these mats or something of the kind, answers this very end. It takes only a few minutes at night to spread the mats in their place, and a few in the morning to lay them aside. But were the labor much greater, the result would amply repay it.—*Agriculturist*.

Seed Saving.

This is the month in which much of this is to be done, both in the Kitchen and Flower Garden. We have frequently impressed upon our readers the importance of saving the very earliest and very best of every variety for seed. Do not pick all the best Sweet Corn, Tomatoes, Melons, etc., for the table, and take seeds for the next crop from what is left. If this be done, we shall have more complaints about sorts running out; they will run out if you help them to do so, but will hold good and even improve if proper care is exercised in seed saving. We know of one variety of Sweet Corn which has been kept in the same family for thirty years without "running out." Some flower seeds require much care to save them. If seeds from Pansy and Phlox are left until the pods are quite ripe, they will all be lost by the bursting of the pods. With plants having seed vessels of this kind, the best way is to pick the flower stems when the seeds are fully formed, but not ripe enough to burst. Placed in a box or on a large sheet of paper in a dry room, they will fully mature, and the seeds may be secured.

Fuchsias in Winter.

A lady subscriber wishes to know why her Fuchsias do not bloom in Winter. The reason is, that it is a summer blooming plant, and they flower so profusely in Summer, that they need a long season of rest. A Fuchsia may be kept during the Winter and an occasional flower be produced, but there are so many freer blooming house plants that it is altogether better to use the Fuchsia as a summer bloomer and give it rest during the Winter. With a green house, young plants can be grown so as to bloom in Winter, but for parlor culture it is best to keep the plants in a state of rest from Fall until early Spring. Then they may be pruned into shape, and brought forward to flower during late Spring and Summer. They do capitally as bedding plants, provided they get a partial shade. Among the new varieties we have found the Comet one of the most valuable.

Prepare for Spring Flowers.

Nothing gives more gratification than the early flowering spring bulbs. These are usually classed under the general term of "Dutch Bulbs," for the reason that they are largely grown in Holland, whole farms being devoted to their culture. This class of plants comprises the Hyacinth, Tulip, Crocus, Narcissus, and numerous others. Dealers are already out with their catalogues for the Fall trade, and it will soon be time for our readers, who intend to plant bulbs, to prepare their ground and select their varieties. If we could have but one spring flower it would be the Hyacinth, so charming in both color and fragrance. To those who can procure them, we say, make a bed of Hyacinths this Fall. A single one, if no more can be had, will be a charming thing in the garden next Spring, but a bed of them is a mass of sweetness

and beauty good enough for any one poor mortal to possess. This last Spring we saw upon the grounds of Mr. Buchanan, at Astoria, a bed about 8 feet wide and 20 feet long, filled with gorgeous blooms of every shade of color. It was certainly worth going far to see.

Then there are Tulips, less sweet and more gay, and Crocusses which so early in Spring lift up their spires of tender green, and then, before we are aware of it, throw out their delicate flowers. Snow Drops, Ixias, the various Lilies, the stately Crown Imperial, and many others, all come under the head of "bulbs," and are to be planted in the Fall. A rather sandy piece of ground does best, which should be enriched by spading in well-rotted manure. The bulbs should be planted in October, rather deeply, Hyacinths and other large bulbs should be put at least 3 inches deep, and two inches is little enough for Crocusses and other small bulbs. In planting, if the colors of the flowers are known, very pleasing effects may be produced by making contrasts of color. Before the ground is frozen, cover the bed with a good coating of stable manure,—no matter if it is coarse. When Spring fairly opens, the manure may be raked off. The bulbs will live year after year, but better flowers will be produced if they are taken up every season after the leaves wither, and allowed to dry until the proper season for setting them out. Most of the bulbs produce a better effect when grown in masses than when scattered through the borders.

Living Window Screens.

A mass of green foliage makes a prettier window screen than any of the costly curtain materials, or those gaily and coarsely painted shades used very generally throughout the country. Whether seen from within or without, they are always in good taste, and lend beauty to the most costly dwelling, and give an air of refinement to the humblest one. The plant best fitted for this purpose is the European Ivy. It is an evergreen with rich dark foliage, grows with tolerable rapidity, and is perfectly hardy. Wherever Ivy is grown out of doors, natural layers may be found already rooted, or it may be readily started from cuttings. It needs a good rich soil and plenty of moisture, but the pot should be well drained. A good way is to fit a moveable shelf to the window sill, and erect upon that a trellis of sticks and wire of such size and shape as suit the fancy. One or two pots of Ivy may be placed upon the shelf and the vines trained to the trellis; this will allow the whole to be moved as occasion may require and it may be placed out of doors during Summer. If placed at a window where the sun is too hot, a simple screen of muslin may be let down between the plant and the glass during the middle of the day. An ornament of this kind costs but little, will last for years, and always be beautiful. A broad leaved variety of Ivy, called *Roegneriana*, is one of the best for this purpose. A plant is very commonly used around New-York as a window plant under the names of Mexican and German Ivy. It is not an Ivy, but is a climbing species of Groundsel (*Senecio mikanooides*), and every way adapted for forming window screens. It is of very rampant growth, and needs frequent pinching to keep it within bounds. It roots with the greatest ease—any piece of stem with a leaf to it will make a plant. Unfortunately it is not generally distributed, but it may be had at the city green houses, and must soon be widely diffused.

Abutilon Striatum.

The Striped Abutilon has long been a favorite of ours. It is almost an ever-blooming plant—good in the house in winter, and a very conspicuous ornament when planted in the grounds. It is a green-house shrub, which will well repay any care that may be given it in Winter, and if put out of doors and left to itself during the Summer, will make a fine growth and give an abundance of flowers. One of its best qualities is the ease with which it is propagated. Cuttings stuck out anywhere, if not constantly exposed to the sun, will grow; they may be propagated in quantities by the method recommended for cuttings in the August *Agriculturist*. The plant has a striking foliage, somewhat like that of the maple. Its flowers are bell-shaped and of a yellow color, strongly veined with scarlet. The pendulous character of the flowers, hanging from long slender foot-stalks, gives them a remarkably graceful character. The plant bears pruning to any extent, and may be grown as a bush, or be trained to suit the fancy of the cultivator. We know of no plant that will give more satisfaction as a parlor plant, than the *Abutilon striatum*. Our engraving will give a good idea of the leaf and flower. The plant may be had at the green-houses, and is frequently for sale in the N. Y. markets in the Spring. *Abutilon venosum*, and *A. insignis*, are fine species, but they require more care than the *striatum*.

Grafting the Grape Vine.

We mentioned in our last number that a new work on grape culture was in preparation by Mr. A. S. Fuller of Brooklyn. In looking over a portion of the manuscript the following remarks upon grafting the vine, struck us as being novel and interesting, and we asked Mr. Fuller's permission to give them to the public in advance of the appearance of his work:

"The propagation of the Grape vine by grafting, is probably as old as its cultivation, and many of the modes practised at the present time, are accurately described in most of the ancient works on gardening and agriculture. But with all the information which we have derived, from both ancient and modern authors,

it still seems to be generally considered a rather difficult if not uncertain method of cultivation. On account of the peculiar structure of the wood of the vine, a lasting union is seldom obtained when grafted above ground, and is far from being certain, even when grafted below the surface by the ordinary method. When we compare the benefits to be derived from grafting the vine, with grafting the pear, apple, etc., it appears to be of little value, because the vine may be readily grown from cuttings of almost any portion of the wood, while the latter produce roots from cuttings only sparingly, even with the greatest care, and under the most favorable circumstances, but they may be propagated very easily by grafting and budding. Thus it appears that nature has provided a way for the rapid multiplication of every species and variety of plants, but she has left it to man to discover the way and means. There are circumstances constantly occurring under which it would be quite desirable to graft the vines; for instance, when we have a new and valuable variety, which we wish to multiply as rapidly as possible; to do this we must produce wood for the purpose, and if we can produce wood more rapidly by grafting than by any other means at command, then it becomes very important to know how to perform the operation successfully. There are usually in every garden where grapes are grown, inferior varieties which it is desirable to exchange for better, and if we employ grafting as a method of propagation, then these otherwise worthless vines may be-

FULLER'S METHOD OF GRAFTING THE GRAPE.

come valuable as stocks on which to graft better kinds; and if by the use of these we can make every bud to produce a shoot of from 5 to 20 feet in a single season, of larger and better wood than we can by any other means, and that too without the aid of any artificial heat, it becomes very important to know how to do it. Sometimes it would be desirable to change a whole vineyard from an inferior variety to a new and superior one, and if the operation is judiciously performed, it can be successfully done, but I will consider this further on. The time generally selected for grafting the vine, is early in Spring, before the vine starts, or after it has started and made a growth of a few inches; both of which I have found highly objectionable; for if grafted early, the operation must be performed several weeks before the vine starts, so as to allow the graft sufficient time to form a union with the stock before the latter starts, or else the excessive flow of sap will drown the graft. This early grafting is very difficult in a northern latitude, where the ground thaws out only a very few days before the sap begins to flow. It is always desirable to graft the grape below ground. If we wait until the vine has begun to produce leaves, and the sap has thickened and flows less rapidly, then by cutting down the vine to receive the graft, we

give it a severe check, which often destroys it, and if not entirely killed, it is so much injured that it does not afford sufficient nourishment to the graft to produce a very strong growth. Besides, if hot, dry weather sets in, the graft is almost sure to fail. These are but a few of the difficulties that I have had to encounter when grafting at these seasons, and in the ordinary manner. To avoid them, I have practised with perfect success the following method: In the Fall, after the leaves have fallen, and any time before the ground is frozen, say in October, November, or December, varying according to latitude, dig away the soil from around the stock (which may be of any size, from one half inch to two inches in diameter) to the depth of 4 to 6 inches; then cut it off, and split in the ordinary manner for cleft grafting; make the graft of one eye with about 4 inches of wood, and insert it in the stock, being careful to have the inner bark of the stock and graft meet, then tie a piece of waxed cloth about it, so as to hold the graft in its place, and keep out the water; next throw in soil enough to fill up around the graft, leaving the bud just above the surface; then put a flower pot (a box will answer the purpose) inverted over the graft, as seen in the engraving; then bank up around the flower pot to the top, but not over it: now put on some straw (a), say 6 inches deep, and cover the earth over all. In this manner the graft is perfectly protected against the frost, and it has all winter to perfect a union with the stock, and by spring it is ready to grow. It should not be uncovered until the cold freezing weather is over. It is necessary that a box or flower pot should be placed immediately over the graft, so that when it is uncovered in spring, the graft will not be disturbed by digging down to uncover it. Grafts inserted in the Fall, in this manner, will make almost as strong a growth as the original vine would have done if it had not been grafted; besides, the operation can be performed at a season when there is usually not so much business as in Spring, and it requires no more skill in its performance than other modes of grafting. When the grafts have made one season's growth, they may be cut down and used for grafts or for cuttings, or they may be allowed to remain until next season, and then be put down for layers."

Laterals on Grape Vines.

Every vineyardist knows that his vines produce in Summer what are known as *laterals*; i.e., branches springing from the axils of the leaves. If they are allowed to have their own way, they sometimes prevent the natural extension of the canes, and fill up the trellis with a showy but useless mass of wood and leaves.

To obviate this, some vine-dressers cut out or pull off the laterals, and they keep up this treatment all Summer long. Is there not a serious objection to this? One office of the lateral is to elaborate and send down nutriment for the infant bud at its base, which bud is designed to be the *fruit bud* of the next year. Now, if we pull off this lateral, we weaken the bud and unfit it for its work the succeeding year; often we cause it to break and send out several weak and watery shoots the present year, and so spoil it for subsequent use. Instead, therefore, of pulling it off, a better way is to pinch off its extremity as soon as it has formed two leaves. If it starts after this, nip off its new growth, and so keep it in check, but do not altogether destroy it. In the Fall cut it off.

Smith thought it would be a fine thing to live in the country. Smith could not get HELP, and as domestic duties began to accumulate and interfere with his ease, Smith set his inventive faculties to work, with the above result.—The contrivance is not patented, but is free for the use of all readers of the *Agriculturist*, for whose especial benefit it was sketched and engraved. We can not speak from personal experience of its perfect feasibility.

Small Leaks in the Household Ship.

A thousand worm holes, that will each admit scarcely a gallon of water during ten hours, will much sooner water-log a ship than a large hole through which is poured in a gallon a minute. In the financial affairs of a family, though the large outgoes may be canvassed and avoided, the whole income may be dribbled away, and no advance be made toward competency, wealth, or position. As a rule, the financial success of any family depends more upon the economy of the wife, than upon the earnings or business income of the husband.—Mrs. Haskell, in her recently issued "Household Encyclopædia," throws together some of the small leaks in a household ship, which we copy for a double purpose; 1st, to show the men that their wives have a multitude of cares, of little details, to look after—generally far more items than occur in man's business pursuits; and 2nd, to perhaps in some cases indicate to housewives details that they may not have thought of before:—"Much waste is experienced in the boiling etc., of meats. Unless watched, the cook will throw out the water without letting it cool to take off the fat, or scrape the dripping pan into the swill-pail. This grease is useful in many ways. It can be burned in lamps mixed with lard; or, when no pork has been boiled with it, made into candles. When pork is boiled alone, it will do to fry cakes, if cleansed. Again, bits of meat are thrown out which would make hashed meat, or hash. The flour is sifted in a wasteful manner, or the bread-pan left with dough sticking to it. Pie crust is left and laid by to sour, instead of making a few tarts for tea, etc. Cake batter is thrown out because but little is left. Cold puddings are considered good for nothing, when often they can be steamed for the next day, or, as in case of rice, made over in other forms. Vegetables are thrown away that would warm for breakfast nicely. Dish towels are thrown down where mice can destroy them. Soap is left in water to dissolve, or more used than is necessary. If Bath brick, whitening, rotten stone, etc., are used, much is wasted uselessly. The scrub brush is left in water, pails scorched by the stove, tubs and barrels left in the sun to dry and fall apart, chamber pails allowed to rust, tins not dried, and iron-ware rusted; nice knives used for cooking in the kitchen, silver spoons are used to scrape kettles, or forks to toast bread. Rinsing of sweetmeats, and skimmings of

syrup, which make good vinegar, are thrown out; cream is allowed to mould, and spoil; mustard to dry in the pot, and vinegar to corrode the cask; tea, roasted coffee, pepper, and spices, to stand open and lose their strength. The molasses jug loses the cork, and the flies take possession. Sweetmeats are opened and forgotten. Vinegar is drawn in a basin, and allowed to stand, until both basin and vinegar are spoiled. Sugar is spilled from the barrel, coffee from the sack, and tea from the chest. Different sauces are made too sweet, and both sauce and sugar wasted. Dried fruit has not been taken care of in season, and becomes wormy. The vinegar on pickles loses strength, or leaks out, and the pickles become soft. Potatoes in the cellar grow, and the sprouts are not removed until they become worthless. Apples decay for want of looking over. Pork spoils for want of salt, and beef because the brine wants scalding. Hams become tainted, or filled with vermin, for want of the right protection. Dried beef becomes so hard it can't be cut. Cheese moulds, and is eaten by mice or vermin. Lard is not well tried in the Fall, and becomes tainted. Butter spoils for want of being well made at first. Bones are burned that will make soup. Ashes are thrown out carelessly, endangering the premises, and being wasted. Servants leave a light and fire burning in the kitchen, when they are out all the evening. Clothes are whipped to pieces in the wind; fine cambrics rubbed on the board, and laces torn in starching. Brooms are never hung up, and soon are spoiled. Carpets are swept with stubs, hardly fit to scrub the kitchen, and good new brooms used for scrubbing. Towels are used in place of holders, and good sheets to iron on, taking a fresh one every week, thus scorching nearly all in the house. Fluid, if used, is left uncorked, endangering the house, and wasting the alcohol. Caps are left from lamps, rendering the fluid worthless by evaporation. Table linen is thrown carelessly down and is eaten by mice, or put away damp and is mildewed; or the fruit stains are forgotten, and the stains washed in. Table-cloths and napkins used as dish-wipers; mats forgotten to be put under hot dishes; teapots melted by the stove; water forgotten in pitehers, and allowed to freeze in winter; slops for cow and pig never saved; china used to feed cats and dogs on; and in many other ways, a careless and inexperienced housekeeper will waste, without heeding the hard-earned wages of her husband; when she

really thinks, because she buys no fine clothes, makes the old ones last, and cooks plainly, she is a most superior housekeeper."—The next time an unthinking husband is disposed to be severe because some trifling matter has been neglected, he should "put that in his pipe and smoke it."

Tim Bunker on Old Style House-Keeping.

It was a rainy morning in August, I had five tons of hay down, and it was "morally certain," as Mr. Spooner says, when he is putting a thing strong, that I shouldn't have any hay weather, so there was nothing to do but set in the house, and see things grow. There is great satisfaction in that, and blessed is that man who has his fields and meadows where he can see them from his window. I have seen some rather handsome pictures down in your city in the Academy, and other places, but there are none to compare with the view from my dining room window. There lies spread out before me, the Horse-pond lot, all nicely mowed, and looking as smooth as Mr. Olmstead's lawns in your Central Park that you think so much of; and just beyond, a four acre field of corn, in full tassel and spindle; and beyond that, a side hill covered with wood and rocks, and a little to the right hand, a glimpse of the sea covered with sails. There is a pasture dotted with cattle and sheep, that beat anything I ever saw on canvass. It don't cost half so much to build a house with the picture gallery outside as it does to have it within, and then you are never pinched for room, and it costs nothing to have your pictures retouched, and the frames regilded. It is a source of endless entertainment and instruction to study this out-door picture gallery, and rainy days give us the leisure, and a new light to see them in.

Mrs. Bunker had got her cheese in the press, and the milk things washed up, and things put to rights generally, when I saw her overhauling a bundle of old yellow papers that looked as if they were a hundred years old. One of them was an old account book of her grandfather's, made by doubling a sheet of foolscap twice, and sewing it together. The thread is stout linen, such as her grandmother used to spin on the linen wheel.

"Now," says she, "Timothy I like to look over these things and see how differently folks live now, from what they used to when my mother was a

girl. Here is the account of my mother's 'setting out in life' when she was married, in the handwriting of my grandfather, Amos Dogett."

"When was that?" I asked.

She read from the manuscript: "Our oldest daughter Sally was married to John Walton Jan. ye 29th 1784."

"That was just after the war of Independence."

She continued "Things that I let my daughter have was one horse 10 pound, one new side saddle and bridle 5 pound." "Horse flesh was pretty cheap then," I remarked. "Reckoning the pound at three dollars and a third, which was its value in the New England States, it would make the horse worth only thirty three dollars and a third, and the saddle and bridle half as much—which is only about one quarter of the price of good sound horses in Hookertown to-day. Side saddles have not fallen off much. They were a good deal in demand then, and not much now. You see Mrs. John Walton, bride, had no other way to get to her new home hut on horseback, and all other brides, and damsels in general, had either to try the saddle or go on foot. Happy was that damsel who could boast of a horse on her wedding day."

Immediately following the saddle was the entry of "one pot 8 shillings, one small iron kettle 6 shillings, one iron spider 4 shillings, one pair of flats." It would seem from this that Mrs. Walton was expected to cook her husband's dinner, and to iron the clothes. Mrs. Bunker says she was a capital cook and laundress. I think it must run in the blood. I have no doubt I am indebted to that pot and spider for all the good dinners I have eaten under my own roof.

Then follows, in the bridal outfit, "two candle sticks, two shillings." These must have been iron, such as went out of date about the time I was a boy. The bottoms of the dilapidated sticks used to figure on hutching day, in scraping off the hair from hogs, and nothing better has been invented since. Then follows "one case of knives, one fire shovel, one large iron kettle, one teapot, one tea-kettle, one trammel." Then for personal adornment the bride had "one gauze handkerchief, 3 shillings sixpence, one pair of gloves same price, one pair of English shoes 6 shillings, one pound of whalebone, and four and a half yards moreen for a skirt," which shows what the whale-bone was intended for. Our grandmothers probably split their own whalebone, and never dreamed of steel hoop skirts.

The fitting out of the bridal chamber was "one feather bed, 4 pound 10 shillings, two under beds, 1 pound 1 shilling, four pairs of sheets, two coverlids, two full bed blankets, one chest and lock, and one looking glass, and one paper of pins." There was no wash-stand with bowl and pitcher, soap dish, and mugs, towel rack, and other indispensable articles in a modern bedchamber. The morning ablutions were probably made in the kitchen, or at the back door from a stone-hollowed out for the purpose. Possibly they kept as clean as those who have better facilities for washing.

The table furniture was rather meager, one set of tea-cups, nine plates, four platters, half a dozen spoons, half a dozen teaspoons, two basins, two porringers. There is nothing said of table linen, and probably Mrs. John Walton was in the height of fashion, not only at tea, but at every meal, eating from a *bare board*. This, I mistrust, was not mahogany or black walnut oiled, but plain pine, or maple, which was scrubbed daily for the whole term of her natural life.

A significant entry was "one little wheel, one pound." This was the linen wheel on which all the sewing thread was spun, and the fine linen for shirts and sheets, and other articles for the bed, and for the person. There was also "one set of loom irons 3 shillings." John was expected to make the loom himself. Fortunately it consisted mainly of wood, and the framing was not difficult. This brings back the good old days of homespun. In that loom was woven all the clothing, woolen and linen, of herself, husband, and children, for a whole generation. What visions of solid work and happiness the loom and wheel open to us.

We find also among the bridal items "hard

money for to buy a cow with, 5 pounds 8 shillings." The *hard* money indicates the abundance of paper currency at the close of the war. The price of cows was relatively much higher than the price of horses. Twice the sum would now buy a very good cow. That cow laid the foundation of John Walton's fortune. His wife understood the mysteries of the dairy, and the one cow grew in a few years into a herd of thirty, and the Walton butter and cheese became famous.

The whole outfit foots up forty-four pounds nineteen shillings sixpence, or less than one hundred and fifty dollars. That stocked a housekeeper in 1784, and probably she was better off than most of her neighbors. The whole would not equal the cost of the piano, now in many a farmer's parlor.

"The tea set that Dea. Smith gave Eliza at her wedding cost \$200," added Mrs. Bunker.

"I know it and the rest of the presents were worth a thousand dollars, to say nothing of the furnished house into which she entered when she got back from the bridal trip."

"A single looking glass costing eight shillings, and a mirror covering half the side of a parlor, and costing three hundred dollars, is another contrast worth looking at," said Sally.

"And the young brides that prink before them are no handsomer or smarter than Sally Walton's daughter, forty years ago."—"It is time you forgot that, Timothy. It is a long while ago."

Here the dinner bell rung and the dingy account book was returned to its place in the bundle.

Hookertown, } Yours to command,
Aug. 10th, 1863. } TIMOTHY BUNKER ESQ.

For the American Agriculturist.

How to Wash Flannels.

"I do hate to wear flannel under clothes," said a gentleman friend, "they chafe so." It was in a mixed company that he spoke, but I thought to myself, if I was acquainted with his sister or wife I'd tell her how to wash the flannels in such a manner that they might not *chafe*. Now flannel is made of animal substance, and is not so easily cleaned as a purely vegetable material, so in our house the flannels invariably form a distinct washing by themselves. Soft water is indispensable. Early in the morning then, we put on the full wash boiler to heat, and for one pair of blankets, throw in horax about the size of a walnut, and cut in a bar of hard soap very fine. When the blankets have a spot here or there, which by accident may have received extra soiling, we take a needle and thread and mark it with a couple of stitches, and rub on a little soap, for without this precaution the spot could not be found after the blankets were wet. We then put them down in a tub and pour the contents of the wash kettle *boiling* upon them. The tub stands for an hour, or until it is cool enough for the hands, when we rub the before-mentioned spots, "souse" the blankets, and wring out. The second suds is prepared as the first, save that only half a bar of soap is required. The third water is clear and boiling, and is designed to cleanse the blankets of the soap of the preceding water, for soap is not healthy for the skin, and if the third water appears *sudsy*, we give them a fourth hot water with a squeeze of blue in it, very little, however, or the blankets will be streaky. And now the quicker they are dried the better, it is very disastrous to have rain come on, or have them snowed upon, or lie overnight; indeed I never wash blankets unless the sun smiles upon me when I am about it. In our way of washing, flannels never shrink, and consequently never get "hard," and as we don't rub them, the nap is left on, they are more comfortable, and wear much longer than when washed in the ordinary way. The colored flannels we put in the tub as we take the white flannels out, having first added a little melted soap; we wash them out right away, as the color will come out by standing. The water must be as hot as the hands can bear, and the soap that is rubbed on about the collars and wrists of flannel shirts, can not be put on when they are out of the suds,

for in many kinds of colored flannel the mark of the soap is left, unless used while the flannel is in the water. Colored flannel does not shrink like white, and for this reason and that the color is likely to come out, we do not use boiling water. In other respects we go through the same process in washing, save that the impression of blue is omitted in the last rinsing. In conclusion, sister readers, use flannel plentifully in your households. In this northern climate, cotton is a very poor substitute. If people paid out as much for flannel as they do for those homeopathic sugar pills, the doctors would be all the poorer, and their own homes all the happier.

Carroll County, Illinois.

MARION.

How to Take Leaf Impressions.

In answer to several inquirers who ask how to take correct copies of leaves, we publish the directions given in "Art Recreations," a manual of ornamental work, published by J. E. Tilton & Co., Boston, Mass.

Hold oiled paper in the smoke of a lamp, or of pitch, until it becomes coated with the smoke; to this paper apply the leaf of which you wish an impression, having previously warmed it between your hands, that it may be pliable; place the lower surface of the leaf upon the blackened surface of the oiled paper, that the numerous veins that are so prominent on this side may receive from the paper a portion of the smoke; lay a paper over the leaf, and then press it gently upon the smoked paper; with the finger or with a small roller, (covered with woolen cloth, or some like soft material,) so that every part of the leaf may come in contact with the sooted oil paper. A coating of the smoke will adhere to the leaf. Then remove the leaf carefully, and place the blackened surface on a piece of white paper, not ruled, or in a book prepared for the purpose, covering the leaf with a clean slip of paper, and pressing upon it with the fingers or roller, as before. Thus may be obtained the impression of a leaf, showing the perfect outlines, together with an accurate exhibition of the veins which extend in every direction through it, more correctly than the finest drawing. And this process is so simple, and the materials so easily obtained, that any person, with a little practice to enable him to apply the right quantity of smoke to the oil paper and give the leaf a proper pressure, can prepare beautiful leaf impressions, such as a naturalist would be proud to possess. Specimens thus prepared can be neatly preserved in a book form, interleaving the impressions with tissue paper. [But we consider all leaf impressions vastly inferior to carefully pressed real leaves themselves.—ED.]

Don't Apologize.

A few months ago one of the Editors of the *Agriculturist*, (who was then *staying*, not *living* in the city, for nobody really *lives* there,) happened to call unexpectedly at a farm house by the sea-side. The good wife in asking him to dinner, apologized for the homeliness of the meal, regretting that she had nothing but clam pie; but "if she had known that he was coming, she would have had fresh meat." If there is anything in the world that *this* Editor is tired of, it is roast beef, and out of any possible bill of fare, that he could have chosen from, clam pie would have had his preference. We mention this to show that country people are much mistaken in thinking they must make a fuss over their city friends. Any change of food is pleasant, even if it is from richer to plainer. If you receive your city friends, give them as good as you have yourself, and don't make them feel uncomfortable by any unnecessary apologies for your fare. If you have only fried pork and potatoes, serve it neatly and eat it thankfully.—We have sometimes sat down to a table, and had our appetite almost destroyed by the hard things said about the food by the one who had spared no effort to make it first-rate.—Our first genuine New-England

Thanksgiving Dinner, was during the first vacation after we went from the West to an Eastern College. A widow lady in good circumstances, invited two of us class-mates to fill at her dinner table, the vacant places of her sons absent as mates of vessels at sea. After eating course after course of excellent food, and becoming literally surfeited, our hostess brought on some mince pie. We begged to be excused, but she instantly replied, "Take some of it, take a little; it is good, I know it is; I made it myself." Of course we did, and praised it too, for it deserved it. Had she, in fishing for a compliment, began by saying it was poor, with sundry reasons why it was so, we should have declined, and she would, ten to one, have been offended that her good pie was not appreciated. We have often referred to this incident, as illustrating the attractiveness of an open frank demeanor, when not accompanied by overweening self-esteem.—Sometimes when our friends tell us the *Agriculturist* is a good paper, we are tempted to say, "we know it is; we made it ourselves."

To Prevent Dampness in Walls.

It is one of the common complaints of those living in stone or brick houses improperly built, that they are damp and unwholesome. This need not be. Those which are damp, are so for the same reason that a pitcher of cold water "sweats" in hot weather. They condense the moisture of the air. The only way to prevent this, is to put some kind of non-conductor between the wall and the air of the apartments. A body of confined air is perhaps the best non-conductor. "Fur off" an inch or two from the solid wall, plaster tightly, and it will keep out frost and moisture better than a foot of solid granite. Even a cellar can be made dry and comparatively healthy by this simple treatment of its walls.

A Word More about Wringers.

From recent observation, we judge this valuable implement is coming into very general use all over the country, West as well as East, and we are glad to find this case, for we believe it to be a real labor-saving implement in the house, where such implements are needed as well as in the field. But we are sorry to see so many persuaded into buying wringers without cogs upon the rollers. We have heard the arguments of different dealers, and personally experimented a good deal with several kinds, and feel quite sure that the cogs are a very desirable addition, to say the least. The cogs compel the rollers to turn together, and this obviates the danger of one of them slipping upon and straining, if not tearing, the fibers when a wad or mass of clothing chances to be passed in. The rubber is also less likely to work loose when cogs are added. We have no interest whatever in anybody's manufacture, and care not whose is sold, but as we understand the matter, we hope the public demand will compel every maker to add the cogs; they will not increase the cost half so much as they will increase the value of the implement.

Wire Clothes Lines.

A subscriber writes from the telegraph office at Carlisle, Pa., that he has for some time used the annealed and galvanized telegraph wire as a substitute for the common clothes line, and finds it to work admirably. He says that it is cheaper than rope, more durable, and as it does not sag the clothes down into the dirt, there is a great saving of the good nature of the women folks. The wire being galvanized, there is no danger of injuring the clothes by rust. From its stiffness, the wire would be unhandy to move, and a line of this kind must therefore be put up permanently.—*Agriculturist*.

REPELLING WORMS FROM DRIED FRUIT.—Francis E. Rumford, New-Castle Co., Del., writes to the *Agriculturist*, that during the past year he has tested

the efficacy of sassafras bark for repelling worms from dried fruit. Two bags of dried apples were placed together in a chest, the one open, but with a few chips of the bark scattered through it, the other closely tied: the latter was infested with worms, the former entirely escaped.

SPIRITS TURPENTINE FOR MOTHS.—A subscriber to the *Agriculturist* writes that during the last of May he sprinkles turpentine on pieces of flannel, wraps these in paper, and lays them among clothing or articles subject to moths: this he says has proved a certain preventive against moths.

Good Way to Keep Smoked Hams.

Good hams, well cured and well preserved, are very convenient to have in the house. They are wholesome food, and are always ready when other meats are absent, or when a hurried, impromptu solid meal is needed. In our travels this summer we have eaten ham in a good many places, at the hotels and elsewhere—some very poor, full of salt and smoke, and then fried to a crisp, and some very good, sweet, tender, fresh, and just cooked through. The best we believe, was met with at Friend Quinby's, at St. Johnsville, N. Y., where we called after the usual dinner hour, and was just in a condition to enjoy a good repast quickly got up. For the benefit of the housekeepers of the *American Agriculturist* Family we enquired the process of curing the hams: They were put in brine in the usual manner last Fall or Winter, and when just fairly salted through, were moderately smoked. They were next cut into slices all ready for the table, and then about half cooked. The pieces were then packed closely into stone-ware crocks, and the lard cooked out poured over them. When there was not fat enough fried out to cover them, some melted lard was added. The crocks were covered and set away, and whenever ham is wanted, it is only necessary to take out a few pieces and finish the cooking, in less than five minutes—with no trouble or time wasted in hunting up and sharpening the knife and saw. We can testify that in the case referred to, the hams were as sweet and tender as could be desired. The method appears to be worthy of general adoption.—We may add here, that nine out of ten housekeepers cook ham too much to leave it either palatable or digestible. It has not a raw taste, if barely heated well through. By the above method of preserving, the salting and smoking need only be carried to just the desired point to make them most palatable.

Hints on Cooking, etc.

Green Corn Pudding.—Contributed to the *Agriculturist* by N. Burwell, Litchfield Co., Conn.: Take 12 good sized ears of corn, grate or shave it off thin, add to it 2 quarts of milk, 1 cup of sugar, a small piece of butter, 2 eggs well beaten, 1 teaspoonful salt, 1 of saleratus, and spice with nutmeg. Bake 3 hours.

Cooking Peas.—Contributed to the *Agriculturist* by Mrs. S. Hubbard, Switzerland Co., Ind. Gather and shell the peas at night, and put them in cold water, in which you have previously thrown a handful of salt. In the morning pour off the water and put them in boiling water. Let them stew for 35 minutes, and then put in $\frac{1}{2}$ cupful of sweet cream, with a piece of butter the size of an egg, and a tablespoonful of flour. Stew for 5 minutes longer—send to the table hot, and you have a dish fit for an epicure.

"Blackberry Flummery."—Contributed to the *Agriculturist* by a "Jersey Farmer's Daughter." Stew blackberries, moderately sweetened with sugar or molasses, until soft; mix a thickening of flour and water, and stir into the berries. Continue stirring while it boils, until the whole becomes incorporated into a mass just sufficiently thick to pour into moulds; when cold turn out for dessert—to be eaten with milk or cream.

To Preserve Tomatoes.—Contributed to the *Agriculturist* by M. A. Goodale, Suffolk Co., N. Y. For 7 lbs. of ripe tomatoes, use half their weight of finely pulverized sugar. Stew $\frac{1}{4}$ pound of green ginger root in water until soft. Remove the skins from the fruit without scalding. Dissolve and boil the sugar in a little water until it is thick, then put in the tomatoes, and take from the fire. When cool, skim them out, heat the syrup, throw in the fruit, until the process is repeated three times. Then add all together, and boil gently until done. Let the syrup become thick before the tomatoes are put in it. Seal the jars with paste made of rye flour, wet with cold water, and keep in a dry place. This will keep all Winter.

Plum Catsup.—Contributed to the *Agriculturist* by Mrs. B. F. Sharp, Geauga Co., O. Boil together for two hours, 9 lbs. plums, 6 lbs. sugar, and 3 pts. vinegar. Just before removing from the fire, add one tablespoonful each of allspice, cloves, and cinnamon. Keep in small jars well corked. The same directions will answer for currants or gooseberries.

Cottage Pudding.—Contributed to the *Agriculturist* by Mrs. S. C. Frye, Merrimac Co., N. H. Mix $2\frac{1}{2}$ tablespoonfuls of melted butter, 1 cup of white sugar, 1 egg, 1 cup of sweet milk, 1 pint of flour, 1 teaspoonful of soda and 2 of cream of tartar; flavor with lemon. Bake in a moderate oven $\frac{3}{4}$ hour.

Sauce, for this or other puddings: 1 egg, $\frac{3}{4}$ cnp of butter, $1\frac{1}{2}$ cups white sugar, $\frac{1}{2}$ glass wine, 2 tablespoonfuls of cream. Set a dish containing it in a vessel of hot water, and stir half an hour. [Many a man has come to dissipation and to a drunkard's grave, by having a taste for alcohol formed while eating a mother's or wife's good wine and brandy sauces.—Ed.]

Economy Cakes.—Contributed to the *Agriculturist* by Mrs. Harne, Hunterdon Co., N. J. Take 1 quart of mashed potatoes, 1 egg, $\frac{1}{2}$ teacup wheat flour, a tablespoonful of butter, and add milk to form a thick batter. Season with pepper and salt. Mix all well together; make into cakes $\frac{3}{4}$ inch thick, and fry brown where meat was previously fried. These can be recommended.

Cream of Tartar Cake.—Contributed to the *Agriculturist* by Lizzie Field, Orleans Co., Vt. Take 3 cns of sugar, 3 eggs, $\frac{1}{2}$ cnp of butter, 1 cup new milk, $\frac{1}{2}$ teaspoonful of soda, 1 teaspoonful of cream of tartar, and 4 cups of flour. Mix the cream of tartar with the flour, and the soda with the milk, and add a little salt. Season to taste. Bake in shallow tins, and cut in squares.

Puff Cake.—Contributed to the *Agriculturist* by "Martha." Take 2 cups of white sugar, 3 eggs, 1 scant cup of butter, 1 cup of sweet milk, 1 teaspoonful of saleratus, 2 of cream of tartar, 3 cns of flour. Flavor to taste. Stir together at once.

Valuable Recipes.—For preserving the complexion: temperance. For whitening the hands: honesty. To remove stains: repentance. For improving the sight: observation. The most valuable ring: the home circle. For improving voice: civility. The best rouge: modesty. The best eye-water: charity. A cure for deafness: attention. A mixture to clear the throat: cheerfulness. A wash for wrinkles: contentment. A general beautifier: contentment.

THE APPLE-PIE MELON.—Our experience with this has not been favorable, but occasionally a subscriber commends it. L. C. Cook, Saratoga Co. N. Y., writes, "it is an excellent substitute for apples, when you 'get the knack' of using it. For pudding I believe any one would prefer it to rice. It makes excellent sweet pickles." Perhaps our correspondent will do a favor by giving her "knack" to the readers of the *Agriculturist*.

MARRYING A GARDENER.—An English writer, in his advice to young married women, says that their Mother Eve married a gardener. But he forgot to add, that in consequence of the marriage, the gardener "lost his situation."

INTRODUCTION OF THE PETS.

Engraved for the American Agriculturist.

Young Animals—Curious Traits.

"This is Miss Daisy, Master Nero, and you must be very kind to her," is what the lad in the picture appears to be saying, by way of introducing his pets to each other. The animals are both evidently pleased with their owner, and under his training will doubtless be very good friends to each other. This managing of pets is one of the pleasantest and most interesting things for young people in the country. It will surprise you to discover how much such creatures may be taught, and to notice the traits of character they will show. By a little care, while young, animals of the most opposite natural qualities may be brought to live together on the best of terms. The writer has seen a dog, a lamb, and a kitten, frolicking together by the hour. Recently he was much interested by the conduct of a dog which was apparently attacking a chicken. He seemed to be biting it with the intention of making a meal of it; but on closer examination it proved that the chicken had been hurt in some way, and the dog was carefully trying to set it upon its feet. Failing in this, he lay down beside it, and commenced licking its wounded leg. A correspondent of the *Agriculturist*, "Lex," relates the following incident. About a month since, two cats had each a "family" within a few days of each other. All the kittens were drowned except two of each set, which, with their respective mammas, were snugly settled in a couple of boxes in the same room. On the following day, both families entire—or rather what remained of them—were found coiled up together in the same box. They were not disturbed, and thenceforward the two mothers ceased to recognize any distinction between the two pairs of kittens. They would alternately nurse the whole lot, or both affectionately entwined together, divide the "labor of love," just as the kittens, lying snugly between them, would happen to turn to the one or the other. But this is not all. Eddie brought a couple of young squirrels from the woods, which soon became very gentle. In less than two days, both were found in the box among the cats and kittens, drawing from either or both the maternal founts, upon a like footing of equality and community with that previously enjoyed by the kittens! The old cats seemed to acquiesce fully in the arrangement, and so it proceeded for a couple of weeks, until one of the squirrels was accidentally killed. The other, having the freedom of the house, is now a romping playmate of both cats and kittens, who continue uniformly to treat him as "one of the family." Many such incidents have come to our knowledge, showing that this department of natural history is not one of the least interesting that can be studied. Our young readers, especially in the country, can find almost endless amusement in experimenting upon it, and at the same time, the patience and kindness they will be required to exercise in order to be successful, will have a

happy influence on their own dispositions and characters, and teach them forbearance toward their own fellows.

An Eccentric Physician.—Anecdote.

A friend relates for the *Agriculturist*, the following anecdote of a skillful physician, Dr. M—, who is still practising in Rhode Island. He had a way of doing things all his own, and no one could tell beforehand, "where he would come out." On one occasion he was called to perform a very important surgical operation on a young man living in the country. Arriving there he found collected a large number of neighboring farmers and others, who had come from curiosity to witness the operation. He observed that the house was scantily furnished, and other evidences of the poverty of the family were apparent, and he inquired whether the mother, a widow, was ready to pay the \$50 which he should charge. She replied that she could not at present, but would do so as soon as possible. The doctor immediately informed the bystanders, that he would do nothing until the money was paid, and asked them if they could not make up the amount. This was soon done, but not without many condemnations of the hard-hearted doctor, who, however, paid no attention to the remarks, but immediately went on with his work, which he performed successfully. As soon as it was over, he stepped up to the mother, and remarking "the boy will need some things before he gets well," slipped the \$50 into her hand, and was off before he could hear her thanks, or the loud praises of those who had just been denouncing him as a grasping miser.

Boys' and Girls' Garden—No. 6.

Perhaps it will be best for our young friends, before they read this garden talk, to look over again the lessons for July and August. We wish you to be perfectly familiar with what is said in July, about the Flax flower. We have taken the Flax as our starting point, our model flower, and you can not have its structure or the "way it is got up," as people sometimes say, too thoroughly by heart. We there showed you the floral envelopes—the calyx and corolla, and the essential organs—the stamens and pistils—in their relations to one another. In August we endeavored to show you how this plan of the flower is varied to produce other shapes, and illustrated this in various ways. We showed you, by means of the Tomato and Morning Glory, that a variety of forms could be produced by the union or growing together of the parts of the corolla, and that in the Pea we had a very different looking flower, by the unequal size of the petals, and the partial union of two of them. In this lesson we wish to continue to show the variations from the Flax, our pattern flower, and to have you see that other parts, besides those of the corolla, can unite more or less into one piece. If you examine the calyx of the Pea, you will see that

the parts or sepals are joined together. So you see that by merely uniting the parts of the calyx and of the corolla in different degrees, we get a great variety of fashions. But this kind of union is not confined to these parts, it extends to the stamens and pistils. The flower of the Tomato will show you one kind of union of the corolla, if you gently separate the stamens, the anthers will be found to be joined together by a thin film or skin. The Pea shows the union of

the stamens in a much more striking manner. Carefully pull off the petals of a Pea, and you will find that the stamens are joined together, not this time by their anthers, but by their filaments. So you see that there are two different ways by which stamens can be united. The united stamens of the Pea form a sort of tube which encloses the pistil, but the tube is not a perfect one. There are ten stamens, but one of these is not joined to the rest, and with a little care you can separate it, leaving nine stuck together and one free. (Fig. 27.) These will answer for illustrations of the several different ways in which the stamens are united.

Fig. 27.—STAMENS OF PEA.

Union between the pistils is very common. We have not said a great deal about the pistil thus far, but this is a most important part of the flower, and we shall say more of it by and by. The pistils vary greatly in number; in the Pea we have but one, and in the Flax we have five, but they are united into a solid body by their ovaries, though their styles are distinct. (Fig. 28.) The pistil of the Morning Glory consists really of three single pistils joined together not only by their ovaries, but by their styles also. There are generally as many cells or divisions in the ovary as there are pistils joined together, and when we cut the ovary of the Morning Glory across, and find three partitions (fig. 29), we may be safe in concluding that it is not a simple pistil, but one formed by the joining together of three so completely as to appear like one. In these different illustrations we have shown the union of parts of the same kind with one another, as of petals with petals, stamens with stamens, etc.

Fig. 28.—PISTIL OF FLAX.

Now we wish to call your attention to a different kind of union, one in which the parts of one set are joined to those of another. This brings us to another set of forms of the flower, and those which often make its structure difficult to understand. Beginning with the floral envelopes, we often find the calyx and corolla cohering together, as will be seen if you examine the blossom of the Melon or Cucumber. A union may take place between the stamens and the corolla. If you split open the flower of the Morning Glory you will see (fig. 30) that the lower parts of the filaments are attached to the corolla. Now this kind of union may go on still further, and the stamens, corolla and calyx, all be united to the ovary. The Melon and Cucumber give us an illustration of this; here (Fig. 31) the corolla appears to come out of the top of the ovary, but really the other parts are joined to the ovary and are free at the top. It is just as if the other parts of the Flax flower stuck to its ovary and only appeared above it.

F. 29. OVARY.

Still other changes are produced in flowers by the absence of one set of parts. You will recollect that it has been stated that the stamens and pistils were the essential parts; if these are present, the flower is a perfect one, and will perfect its seeds no matter if the corolla or calyx or both are absent. There are many flowers which have a calyx and no corolla, and many others which have neither. Among our plants chosen for illustration, the Oat has neither calyx nor corolla.

It is rather late for you to examine the flower of the Oat, but you may, perhaps find some among the stubble of the oat field. Here we have neither calyx or corolla, but green scaly, or chaffy parts called *glumes*. Fig. 32, will help you to understand the flower of the Oat. Beginning below you have a pair of empty scales, and within these two pairs of scales, and inside of these pairs you will find the pis-

Fig. 30.—COROLLA OF THE MORNING GLORY—OPENED.

til and stamens. One of these scales usually bears a beard or bristle as shown on the right hand of the Oat figure. Though the flower of the Oat has neither calyx nor corolla, it has both stamens and pistils, hence it is *perfect*. Where either stamens or pistils are absent, the flower is *imperfect*. In the Melon and Cucumber, and all of the Squash family, the stamens are contained in one flower, and the pistils in another. In each vine some of the flowers have stamens only, and are *staminate* or *sterile*, and other flowers have pistils only, and are *pistillate* or *fertile*. Fig. 31, represents the pistillate flower of the Cucumber, and fig. 33, the staminate flower. The pistillate flower is easily known by its having its ovary apparently below the corolla, this contains no stamens. The staminate flower, fig. 33, has no pistil, but stamens only, and these in this particular family of plants, are not only united, but the anthers are bent up in a most curious manner as shown at the left hand of the figure. In the Melon, Cucumber, Squashes, and all plants of that family, we have the staminate and pistillate flowers both in the same plant, but there are many cases in which these are in separate plants, and separated still further, as in the Hemp, Hop, Willow, etc. Now we have already stated that the ovary—the lower part of the pistil—contained the ovules which were to become seeds, and that these would never be perfected unless the pollen—the fine powder furnished by the anthers—came in contact with the stigma. When the stamens and pistils are both in the same flower—as in the Flax—this contact of the pollen, or *fertilization* as it is called, can readily

take place; but in the case of separated flowers like the Melon, etc., the pollen has to be carried to some distance before it can reach the pistils. The pollen grains (mentioned in the July lesson) are finer than the finest dust, and are readily blown about by the winds. This is one way in which pollen can pass from a staminate to a pistillate flower, but insects also play an important part. Bees especially, enter flowers for their sweet juices, which they convert into honey, and for pollen, which they use as food for their young. Every one has noticed how busy bees are among all the plants of the Squash family, to which the Cucumber and Melon belong. They go about from flower to flower in search of food, and at the same time they carry pollen from the staminate to the pistillate flowers, and thus render the plant an important service. We have probably said enough about the various shapes which the flower assumes, to enable you to find out in all our wild flowers, and in all the cultivated *single* ones the real position of the parts. Generally you will find that flowers differ from the Flax in the union of parts of the same kind, the unequal size of parts of the same kind, the union of parts of different kinds, or the absence of either corolla, stamens, or pistils. We do not expect to teach you every thing about plants in these lessons, but hope that you will, by a thorough study of the illustrations we have chosen, get such a general idea of plants, and see that there is so much about them that is worth studying, that you will, another year, take up some hook on the subject, that will give you a more thorough knowledge than we can impart in these short lessons.

Fig. 31—Pistillate flower of the cucumber.

Button-Hole Scissors.

Here Boys, is something useful which you can make for your mothers and sisters. It is not a new affair, though most things are *new* to boys. The one from which this little picture is sketched, was made *forty nine years ago*, and is good yet! An aged friend of ours, whose "Golden Wedding" occurs next April, soon after he was married, took an old broken-pointed pair of scissors and filed a notch out of each blade, close to the joint, as you see in the engraving. The ends were then ground off so as to leave about half an inch of cutting blade, or just enough to cut the smallest button hole. Larger holes can be made by a second cut with the blades. The next time you see mother or sister trying to make a button-hole with a knife or a chisel, if you can find an old broken pair of scissors or shears, go privately and get them up something convenient, like that described above. Be careful not to let the file touch the cutting edges to be left, for they should be sharp. The notches should be $\frac{1}{2}$ to 1 inch long, so as not to cut the edge of the cloth.

No. 50. Illustrated Rebus.—A truin too often forgotten.

No. 51. *Mathematical Problem*.—The following was contributed to the *Agriculturist* by Benjamin Albertson, Bucks Co., Pa., unaccompanied by any answer. From a hasty examination, it appears to us that not enough conditions are given for its solution; but we submit it to the mathematicians among our readers, for their decision. "A. B. and C., with their wives, P. Q. and R., went to market to buy pigs. Each man and each woman bought as many as they gave shillings for each pig. A. bought 23 pigs more than Q; B. bought 11 more than P.; also each man laid out 63 shillings more than his wife. Which two persons were man and wife?"

Questions to Teach Observation.

Do cats and dogs have the same number of claws or nails on each foot? What is the difference in the manner of cattle and horses rising, after lying down? What is the difference in the teeth of horses and cattle? How many have each? How many has the sheep? Answers to these need not be sent in, as all can ascertain them by simply examining for themselves.

Answers to Problems and Puzzles.

Answers to Problems and Puzzles in August number, (page 249). No. 47. *Illustrated Rebus*.—He bears (or she bears) the palm, that ch ear full y follows duty; or, He bears the palm that cheerfully follows duty. No. 43. *Arithmetical Problem*. He travels 40 miles an hour in going, and 25 miles an hour in returning. No. 49. *Arithmetical Problem*, has thus far received no answers by our readers; we therefore leave it unanswered for another month. *Note*.—In printing the answer to No. 46, last month, the figures were accidentally reversed. It should read, A, should receive \$98 and 232-331; B, \$171 and 99-331. The last figures are fractions, not cents and decimals, as some misunderstood.

No. 52. *An Enigma*.—Contributed to the *American Agriculturist* by W. Painter, Harford Co., Md.

I'm a mystical word as you may perceive,
And oft appertain to the daughters of Eve:
My plant good nature no mortal may doubt,
For I still am the same, tho' you turn me about.

If you cut me in twain each part you will find
Is composed of materials of just the same kind.
Divide me in three, and, if rightly disposed,
Of a double each portion you'll find is composed.

Though intended by Nature for care and protection,
You would think that I oft stood in need of correction,
For sometimes asunder I rudely am torn,
And to far distant countries each portion is borne;

One half you will find in the far distant South,
In a Town by a river not far from its mouth;
While the other (oh! shame that I thus am abused,)
In a Town far in Europe is constantly used.

Like true love that burns with a still constant flame,
My beginning and ending are always the same;
And to make you more closely my case understand,
I may say that my half is now fast in your hand.

Partial List of

PREMIUMS for 1864.

Or Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the *American Agriculturist*.

(Premiums open to all—No Competition.)

Owing to the greatly increased cost of everything connected with publishing, and our determination not to raise the subscription price, and not to diminish the intrinsic value of the paper, but rather to improve it, we had expected to give no premiums hereafter, excepting the Great Strawberry which will be a premium to every subscriber, and ought to be enough to secure as many subscribers as could be desired. But the previous plan has worked well, and many of those who have obtained premiums hitherto, express a strong desire to have an opportunity to get some of the higher premium articles. After looking the ground all over, and making a careful estimate, we have decided to offer one general list, as named in part below. The list of premiums is not yet made up, as we have not completed our arrangements with manufacturers, nor fully tested some new articles proposed to be added. Next month the list will be full. Any articles added to the present list, will be at about the same terms as to cost, number of subscribers, etc. We solicit any suggestions as to the premiums, if sent very soon. As many want to begin canvassing now, so as to take advantage of the special inducements now offered, of extra copies (see page 283,) and of an early place on the strawberry list, etc., we give the partial list of premiums this month. Therefore, any one desiring to do so, can go to work at once, and perhaps this very month get names enough for a good premium. All names sent in now, get both the strawberries and the three extra numbers. Note that in all cases the five cents extra are needed when the "Agriculturist Strawberry" plants are desired. This will, of course, be paid by the subscribers themselves.

The names (with money for each,) can be sent in as fast as gathered, so that the subscribers can begin to receive their papers; the premium will be paid to any one as soon as his list is completed. **But, let it be distinctly noted, we can reckon for premiums only those names, which are marked as for Premiums when they are sent in.** Hereafter all the separate names thus sent and marked as for premiums, will be at once numbered in a special book, with the name of the sender, so that we can at once turn to a canvasser's list, and see when it is full.

Premium clubs need not necessarily be all at one Post-Office. Each list ought to contain a fair proportion of new names, for it is to bring the paper before new subscribers, that the premiums are in part intended.

N. B.—Every article offered, is a good one—nothing second-hand or of poor make, or quality, or kind. We intend in all cases to deal fairly with every one, and esteem as special friends those who labor to promote the interests and circulation of this journal.

This list may perhaps be altered or amended from time to time, if circumstances or change of prices, etc., require, but all names sent in during any month, will be reckoned at the premium rates announced for that month.

We have not space to describe the premiums this month. Every article is really worth having. The Clothes-Wringer is a capital thing, and ought to be in every family, as a labor-saver and a clothes-saver. The other articles are also all excellent.

Table of Premiums for 1864.

Names of Premium Articles.

Names of Premium Articles.	Price of Premiums.	Names at 10 cents each.	Names at 25 cents each.
A—Goon Books—See terms below	10	45
B—Best Family Clothes Wringer \$7 00	40	90
C—Nonpareil Washing Machine \$16 00	98	195
D—Sewing Machine, (Wheeler & Wilson) \$45 00	82	185
E—Sewing Machine, (Wilcox & Gibbs) \$40 00	20	63
F—Woodruff's Mercurial Barometer \$8 00	30	91
G—Woodruff's Mercurial Barometer \$12 00	25	67
H—The Aquarius \$10 00	170	340
I—Five Octave Melodeon (best) \$20 00	120	234
J—Four Octave Melodeon (best) \$35 00	25	68
K—Seven back Volumes <i>Agriculturist</i> \$25 00	25	64
L—Six do do do \$20 00	22	49
M—Five do do do \$15 00	19	42
N—Four do do do \$12 00	13	24
O—Three do do do \$10 00	13	24
P—Two do do do \$8 00	13	24
Q—One do do do \$5 00	13	24
R—Jacob's Portfolio Paper Felt \$1 50	17	17
S—Osborn & Hodgkinson's Paints \$1 50	17	17
T—Premium Cylinder Plow \$20 00	23	75
U—Eagle Plow No. 20 \$25 00	23	69
V—Hay and Straw Cutter (best) \$20 00	23	65
W—Steel-tooth Cultivator (best) \$20 00	23	58
X—Family Lard and Wine Press \$7 00	24	51

***Books**.—Any person sending in 25 or more subscribers, may select from our book list (page 283) to the amount of 10 cents for each name sent in at the club price of 80 cents, or to the amount of 30 cents for each name at \$1. (No books sent for less than 25 names.) The premium books will be delivered anywhere in the United States, or to the border of the British Provinces, free of all cost, by mail or express. Many Farmers' Clubs have, by means of this premium, obtained a good library.

The Domestic Produce Markets have been exceedingly dull the past month, owing in part to the extreme heat, but especially to the great decline in the relative value of gold as compared with currency. We have repeatedly shown that the high premium on gold was directly advantageous to farmers; so the fall in gold disturbs nominal prices and reduces the demand for export. With the fall of gold the value and demand for breadstuffs to export is diminished. The expected fall of Charleston has led dealers, and especially exporters, to anticipate a still further decline in gold, and hence they have been unwilling to buy breadstuffs. The tables above show the amount of sales, and of receipts, the latter diminished in part by a break in the Erie Canal. Really good lots of new flour, grain, and of mixed corn are yet scarce, and the market for these is firm. The Oats and Rye received have mostly been greatly inferior, and difficult to sell. Not much done in Barley at this season. Cotton advanced moderately, but closes tame, and prices tending downward. Provisions unsettled, by fall in gold—the chief inquiry being for hog products. Wool is similarly affected by gold, and buyers are shy of purchasing. The auction sales, Boston August 4th, and in New-York Aug. 12th, were spiritless; the sales at low rates. Hops are in good request at full prices, owing to unfavorable reports from the chief growing districts. Hay scarce, in good demand, and at firmer rates. North River Bale Hay closes buoyantly at 90c. @ \$1.15 per 100 lbs. Tobacco has been more freely purchased at easier prices. In most other Agricultural products the transactions have been limited. The table below will show the changes in prices and the present rates.

CURRENT WHOLESALE PRICES.

	July 18.	August 19.
FLOUR—Super to Extra State	\$4 00 @ 5 50	\$3 85 @ 5 25

TOMATOES, per bushel		50 @ 75

N. Y. Live Stock Markets.—The Cattle markets have been fairly supplied during the past few weeks, the average being 5,247 head per week. With a lessened demand in hot weather the city prices fell 3/4c. per lb. the second week and 1c. more at the next market. Only 3,990 bullocks were received during the next week, and prices went up 1c. without supplying the demand. For the week ending August 18th the very large number of 6,302 were received, and over 6,000 sold at a decline of 3/4c. from the previous week. This was the largest supply since September of last year. Prices ranged from 10c.

to 10½c. per lb. estimated dressed weight for prime animals; 6½c. for poor as to quality, to good.

SHEEP AND LAMBS are selling well at 5c. @ 6c. ½ lb. live weight. Lambs 7½c. @ 9c. Store sheep \$3½ @ \$4½ each.

Washing Machine not endorsed.

We have seen a handbill of a washing machine, invented by "Wm. M. Doty, late Associate Editor of the American Agriculturist." Lest this should imply any endorsement, we would say, that we have not proved the machine, and can not speak *pro* or *con*. Mr. Doty was formerly employed temporarily in this office, assisting in the business and editorial departments, but this has nothing to do with the merits or demerits of the machine, and should not be so used or construed.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.

Fifty cents per line of space for each insertion.

One whole column (15 lines), or more, \$50 per column.

Business Notices, Eighty cents per line of space.

BEAUTIFUL COUNTRY HOMESTEAD Near New-York City.

All finished and ready to be enjoyed without further care or trouble.

A very desirable Homestead, of nearly 2 acres, within fifty minutes ride from Wall-st.,—hourly communication from 6 A. M. to 7½ P. M. and at 11 P. M.

The Buildings are commodious, and the grounds are fitted up in the most complete order, with every desirable kind of shrubs, trees, fruits, etc., etc.

In short, it is just such a place as any one would desire to enter upon and enjoy without further trouble. Good Churches and Schools very convenient.

It will be sold for less than it cost in gold currency.—Price \$17,000, which may be reduced by sale or reservation of three or four valuable building lots, if the whole ground is not wanted. Part of the purchase money may remain for a term of years if desired. For full particulars, inquire at the *Agriculturist Office*, 41 Park Row, New-York.

THE CHAMPION. HICKOK'S PATENT PORTABLE KEYSTONE CIDER AND WINE MILL. 10,000 in Use and Approved.

This admirable machine is now ready for the fruit harvest of 1863. It is, if possible, made better than ever before, and well worthy the attention of all farmers wanting such machines.

It has no superior in the market, and is the only mill that will properly grind Grapes. For sale by all respectable dealers.

If your merchant does not keep them, tell him to send for one for you, or write to the manufacturer yourself. Address the manufacturer, W. O. HICKOK, Eagle Works, Harrisburgh, Pa.

GRAPE VINES.

Planters and Dealers will please send to WM. PERRY & SON, BRIDGEPORT, CONN., for their price list for 1863. CONCORD and DELAWARE Vines of superior quality, at low rates.

TREMBLEY'S UNION STRAWBERRY PLANTS. Sent by Mail until the 1st of Nov. Postage 10c. for 2 dozen and under, or 25c. per 100. Mode of cultivation with each package post paid. Address S. K. TREMBLEY, Bergen Point, N. J.

WANTED TO RENT, by a practical FRUIT GROWER, a small place of 10 to 20 acres, good soil and buildings. Within 2 hours of New-York by steam boat, New-Jersey preferred. Address with particulars "FRUIT GROWER," care of American Agriculturist, 41 Park-row, N. Y.

SEWARD FEMALE INSTITUTE.—Hon. Wm. H. Seward, President—Miss Mary E. Hotchkiss, Principal. Winter Session opens October 19th. Board and tuition—English and French, \$140 per year.

Location Florida, Orange Co., N. Y. References Rev. James Ellis, D.D. Brooklyn, and R. G. Pardee 593 Broadway, New-York.

GRINDS RAPIDLY.

SEND FOR DESCRIPTIVE CIRCULAR, and address

WM. L. BOYER & BRO., Philadelphia, Pa.

J. C. Taylor, Holmdel, N. J., Breeder of Webb South Down Sheep.

Would say to the readers of the *Agriculturist*, after 15 years experience, that no sheep for mutton, wool, easy keeping and as a cross, either to produce wethers or early lambs for the butcher, can equal the South Down, and that no South Down has reached the perfection of the Webb South Down. Having made it my constant aim to stand ahead of all other breeders for 9 years past, and procured of Mr. Webb his very choicest stock animals by much effort and fabulous prices, I now claim to have a flock that has no superior in England or America, and now offer rams, ewes, ram lambs, and ewe lambs for sale, at prices according to quality and age, from \$22 to \$150 each.

Wishing to show my flock to all: Persons leaving either New-York or Philadelphia at 6 A. M., on Camden and Amboy R. R. for Freehold, can reach my place at 11 A. M., examine my sheep 2½ hours, and reach either city the same evening. The Keyport boats now leave foot of Robinson-st. at 4 P. M., in a few weeks at 3 P. M. Inquire at *Agriculturist* office of H. B. LANE.

Saratoga Springs Remedial Institute.

THIS INSTITUTION WAS ESTABLISHED TO MEET the wants of a class of Patients who feel the necessity of leaving their homes for medical aid. Its location was chosen in view of the medicinal advantages of the Springs.

Since graduating at the New-York Medical University, we have availed ourselves of the facilities found only in our large cities for the study of disease, and have given special attention to those of Women; also, of the Throat, Heart, and Lungs.

As medical practitioners we treat all diseases; but Chronic Affections claim our principal attention.

While this is not a Water-cure, the invalid will find a good gymnnasium, and all the facilities of a well-conducted scientific Hydropathic Establishment.

The home reputation of a physician should be the basis of public confidence. For a fuller knowledge of the Institute, we refer to our Circular, and the reliable citizens of our village.

The medical profession are invited to acquaint themselves with the Institution.

LINDLEY & HINKS,

"Bridgeport Nursery" Bridgeport, Conn.

FRUIT TREES, &c., &c. AT LOW PRICES.

FROST & CO., GENESEE VALLEY NURSERIES, ROCHESTER, N. Y., offer for the Fall of 1863 and Spring of 1864, a well grown and large stock of STANDARD and DWARF FRUIT TREES of all kinds. Also an immense quantity of SMALL FRUITS, including an extensive collection of the rarer sorts of NATIVE GRAPES;—also of ORNAMENTAL TREES, including a large stock of various sizes of HARDY EVERGREENS; also SHRUBS, ROSES, GREEN-HOUSE PLANTS, &c.

Their Nurseries comprise upwards of THREE HUNDRED ACRES, so that they are enabled to furnish the ENTIRE orders of their correspondents fully and satisfactorily, and at the LOWEST MARKET RATES for plants of the best quality. DESCRIPTIVE PRICED CATALOGUES: No. 1, of Fruits, No. 2, of Ornamental Trees, &c., and No. 4, Wholesale List, are supplied to applicants upon receipt of a 3-cent postage stamp for each. Their WHOLESALE CATALOGUE for the FALL of 1863, is now ready for distribution. All communications promptly noticed. Address

FROST & CO., Rochester, N. Y.

FRUIT AND ORNAMENTAL TREES. RARE CHANCES OFFERED.

200,000 Choice Fruit Trees, Vines, etc., for sale, of varied size to suit customers. The subscriber calls attention to his unusually large stock of well grown trees now on hand, and especially to the present stock of the STANDARD FRUIT APPLE, which is the largest and finest ever offered at these Nurseries.

With twenty years of experience, by careful observation and judicious selections, he believes he is able to judge and furnish what will suit his customers, as well as the varied soils and localities, in which trees may be wanted. There is also special attention paid to local varieties, adapted to Southern and Central Pennsylvania, many of which have proven themselves more valuable, than sorts originating in a climate differing so widely from these sections.

He is also preparing a list of CROWN PRICES for those who purchase direct from the proprietor, offering rare inducements for neighbors to join together and get trees considerably under the regular retail prices.

This mode is adopted for those who may not have an opportunity to purchase from his regularly authorized agents, and hold a mistrust towards the too numerous tree vendors spread over the land.

The frequent use made of his name and establishment by strangers, to effect sales where the reputation of the nursery is known, compels him to warn all not to purchase—as coming from these Nurseries—stock offered by pretenders, who do not hold an authority from the proprietor.

Local or stationed agents will be accepted, but neither traveling nor stationary agency inquiries will receive notice, unless the parties produce satisfactory reference as to their honesty in dealing with customers and employer. Send for Catalogues and priced List, which contain inducements not before offered by him. ADDRESS AND TRUSTWORTHY REFERENCE WILL BE FURNISHED TO ALL WHO ARE STRANGERS TO THE ESTABLISHMENT.

Address DAVID MILLER, JR.,
Cumberland Nurseries, Carlisle, Pa.

Delaware Grapes.

After some years of experiment, the subscribers have adopted a mode by which they can produce plants of this valuable grape with abundant fibrous roots at the following very low rates:

1st Class, \$25 per 100, } 2nd Class, \$15 per 100.
\$300 per 1000, } \$100 per 1000.

Of these one year old, they can furnish 50,000 deliverable in October and November.—These vines are not grafts, but are raised direct from cuttings.

Those who wish to plant largely will do well to examine this Stock before purchasing, and to send their orders early as the demand last year exceeded the supply.

Those who wish can also see THREE ACRES of Delaware Vineyard in full growth.

CONCORD and other Grapes furnished by the 100 or 1000.
Address PARSONS & CO.,
Flushing, N. Y.

GRAPE VINES.

New and Splendid Strawberries

The prize berries of Europe, Empress Eugenie, Marguerite and Princess Frederick William, plants \$1 per dozen.

Russell's Great Prolific. One of the most promising of the American seedlings, berries produced this season, 6½ inches in circumference; it is more prolific than the Wilson, superior in flavor, and a splendid market berry, \$1.50 per dozen, or \$9 per hundred.

Lennig's White, Albion White, White Pine Apple, and Deftford White. These are great acquisitions, berries very large, fine flavored and very productive, at \$1 per dozen.

La Constante. We would call attention to this variety, as one of the most promising sorts in cultivation, at 50c. per dozen, \$4 per hundred.

Oscar, Victory, Wizard of the North, River's Eliza, Boite de St. Julien, Crimson Queen, Wonderful, Filbert Pine, Prince Imperial, Duc de Brabant, Boyden's Mammoth, and Duc de Malakoff, at 50 cents per dozen.

Triomphe de Gand, Great Austin, Jenny Lind, Bartlett, Felton, or Chilian, at \$1 per hundred, \$6 per thousand. Berries of the Great Austin were produced this season, weighing 1½ ounces. We think the Austin better than the Wilson, and more productive. Plants delivered in rotation as ordered. All orders addressed to
WM. S. CARPENTER,
329 Greenwich-st., New-York.

Green Prolific Strawberry.

Produced from "Kitley's Goliath" and "Hovey's Seedling," by Seth Boyden, Esq., and is one of the parents of his famous seedling "AGRICULTURIST" which astonished the natives at the late exhibition in New-York. In many points equal to this wonderful new variety. Decidedly one of the best in cultivation. Strong Plants \$1 per dozen. For a descriptive circular or plants, Address

J. KNOX,
Box 153, Pittsburgh, Pa.

Sanford & Mallory's PORTABLE

Flax and Hemp Dresser.

This implement gives one fourth more dressed fiber, and of better quality than any other machine; is simple in construction and strongly made; can be operated by any common laborer; can be driven by ordinary horse power, and the largest size occupies only about four feet square.

PRICES.—No. 1 Machine, to dress 2500 lbs straw in 10 hours \$355; No. 2, \$255; No. 3, Hand Machine \$155, delivered at the factory. Read the following:

MALTA, Saratoga County, New-York, August 10th, 1863.

MESSRS. MALLORY & SANFORD:—

Gentlemen: On the 19th day of March we drew to the mill of N. G. Akin thirty-nine hundred and thirty (3930) pounds of flax straw, which he dressed through the Old Brake, and we received four hundred and eighty-one (481) pounds dressed flax.

We, about the first of June, drew to the mill of Wm. H. Buckley forty-four hundred and ten (4410) pounds of flax straw, which was dressed through one of your Patent Flax Brakes; we received eight hundred and five (805) pounds of dressed flax.

The flax was grown on the same piece of land, and there was no perceptible difference in the quality of the flax, except that the portion drawn to Akin's mill was rotted in the Fall of 1862, and that drawn to Mr. Buckley's Mill was spring rotted, which is considered not as good, from the fact that it loses part of the oily matter from the fiber, and thus not yield as much per ton of straw as the fall rotted.

You will perceive by the above statement that we received from Mr. Akin's mill 245 pounds nearly of dressed flax per ton of straw, and from Mr. Buckley's mill 365 pounds of dressed flax per ton, which makes a difference of 120 pounds per ton in favor of your Brake.

We are recommending our neighbors to take their flax to one of your Brakes to have it dressed, although it is fifteen miles to the nearest one at present.

J. B. WEEKS.

L. L. WEEKS.

I certify that the above statement is correct, as I saw the Weigher's receipts for both lots of straw, and weighed the dressed flax myself that was dressed at my mill. The flax dressed at Mr. Akin's mill is correct, no doubt, as the above gentlemen are perfectly reliable.

W. H. BUCKLEY.

TOBACCO.

Just How to Grow it.

Every particular, from the selection of the Seed, and preparation of the ground, to the Gathering, Curing, and Marketing the Crop, is given in a work issued by the Publisher of the *American Agriculturist*, and sent post-paid for 25 cents. This work consists of a selection of the best fourteen out of eighty-five Essays, prepared by eighty-five different cultivators, residing in various parts of the Northern and Middle States. In each of the Essays contained in this work, the writer tells, in a plain, practical, straight-forward manner, just what to do, and how to do it. Any item omitted by one is given by another, so that the information is full and complete. Several engravings illustrating the method of drying, packing, etc. The work is worth its weight in silver to every one growing even a small plot of tobacco.

MME. DEMOREST'S MIRROR OF FASHIONS.—The Fall Number and commencement of the fourth volume, ready Sept. 1, will contain five useful, full-size patterns, worth 75 cents; a splendid and large parlor engraving of Empress Eugenie and Her Maids of Honor, worth twice the cost of the magazine; a splendid colored Fashion Plate; a large Sheet of Braid and Embroidery Patterns, and many other valuable novelties too numerous to mention. Single copies, 25 cents. Yearly, \$1, with 50 cents worth of extra patterns of your own selection, and an excellent Carte-de-Visite of the Lilliputians, as a premium; postage on the premiums, two cents extra. To all new subscribers who commence with the Fall Number, the present Summer Number will be sent free, if requested.

FORM OF AN ORDER.—Mme. Demorest will find inclosed \$1, and two cents postage on the premiums, for which please send me your Mirror of Fashions for one year, commencing with the Fall Number; also send the Summer Number, and oblige yours

Give your address in full, and address it to

COOK'S

SUGAR EVAPORATOR,

MANUFACTURED BY
BLYMYER, BATES & DAY,
MANSFIELD, OHIO.

IT IS CHEAP.	No machine of only five year's standing can show so brilliant and useful a record.
IT IS DURABLE.	\$2,000,000.00 SAVED BY IT LAST YEAR!
IT IS A DEFECATOR.	Committees pronounce in its favor
IT IS A REFINER.	Operators pronounce in its favor.
IT BOILS RAPIDLY.	Lovers of good syrup pronounce in its favor.
IT BURNS LITTLE FUEL.	The People pronounce in its favor and declare it
IT IS CONVENIENT.	THE CHEAPEST, THE BEST,
IT IS CLEANLY.	THE MOST DURABLE, THE MOST RAPID,
IT MAY BE PORTABLE.	THE MOST ECONOMICAL, THE MOST CONVENIENT,
IT MAY BE STATIONARY.	Ever brought out in the history of Sugar Making.
IT IS EASILY MANAGED.	Its superiority is admitted by all manufacturers over every other Evaporator than their own!
	The "SORGO HAND BOOK" sent free on application.

A GREAT BOOK FOR AGENTS!

DR. RANDALL'S new work on SHEEP HUSBANDRY, recently announced as in preparation, is now in press, and will be published early in Sept. It is entitled THE PRACTICAL SHEPHERD, and must prove the BEST and MOST COMPLETE practical work on the subject ever published in America. The demand for a good Sheep Book is great, and this one is designed to supply it fully. Its sale must be immense in all parts of the country where sheep are kept. The book will be furnished to Agents on such terms that they can not fail to make money rapidly by its sale. Enterprising canvassers wanted in every County—such as will attend to the business thoroughly. For circulars containing terms and other particulars, address

BAKER'S PATENT FRUIT JARS. WITH EITHER GLASS OR TIN COVERS.

They are SIMPLE, RELIABLE, and CHEAP, and the ONLY Jar of which there are NO COMPLAINTS. From the great number of testimonials we might give, we only quote from the "AMERICAN AGRICULTURIST," which says: "They are the BEST of the TWENTY-ODD KINDS WE HAVE TRIED."

Housekeepers try for yourselves. Do not be persuaded to try others, for it will be to your cost. For sale by all respectable dealers.

The trade supplied by the
MANUFACTURERS AND PROPRIETORS,
F. L. & F. N. BODINE & CO.,
Successors to POTTER & BODINE,
106 Chestnut-st., Philadelphia, Pa.

TO THE LADIES.

We desire to call your particular attention to MASON'S PATENT SELF SEALING
FRUIT JARS AND CANS.

An experience of six years has proved them the most perfect Jars for preserving fruits and vegetables. Sold by all dealers. Made only by the **SHEET METAL SCREW CO.,**
214 Pearl st., New-York.

Portable Printing Offices.

For the use of Merchants, Druggists, Nurserymen, and all who wish to do their own Printing. Circular sent free. Specimen Sheets of Type, Cuts, &c., on receipt of two 3c. stamps.
ADAMS PRESS CO., 31 Park Row, N. Y.

ANTI-FRICTION HORSE POWERS, AND BURR STONE MILLS,

which may be driven by
HORSE, WATER, or STEAM POWER.

Send for Circular to
E. H. BENNET,
42 and 41 Greene-st., New-York.

The NONPAREIL WASHING MACHINE

Is the only entirely reliable machine in use. It has been before the public two years, and has not in any instance failed to give satisfaction. It saves two-thirds the labor and time required in hand washing. It is a squeezing machine, and will not injure the finest clothing. A girl of fourteen years can operate it. It will not get out of order. It is recommended by Mr. Judd, the proprietor of this Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20.
Send for free Circular to
OAKLEY & KEATING, 73 South-st., New-York.

GREAT DISCOVERY!

Applicable to the useful Arts.

A new thing.

Its Combination.

Boot and Shoe Manufacturers.

Jewelers.

Families.

It is a Liquid.

Remember.

Finis.

**USEFUL and VALUABLE
DISCOVERY!**

**HILTON'S
INSOLUBLE CEMENT!**

Is of more general practical utility than any invention now before the public. It has been thoroughly tested during the last two years by practical men, and pronounced by all to

**Be Superior to any
Adhesive Preparation known.**

Hilton's Insoluble Cement

Is a new thing, and the result of years of study; its combination is on

SCIENTIFIC PRINCIPLES,

And under no circumstances or change of temperature, will it become corrupt or emit any offensive smell.

Boot and Shoe Manufacturers, using Machines, will find it the best article known for Cementing the Channels, as it works without delay, is not affected by any change of temperature.

Jewelers. will find it sufficiently adhesive for their use, as has been proved.

It is especially adapted to Leather, and we claim as an especial merit, that it sticks patches and Linings to Boots and Shoes sufficiently strong without stitching.

**IT IS THE ONLY
LIQUID CEMENT**

Extant, that is a sure thing for mending **Furniture, Crockery, Toys, Bone, Ivory,** and articles of Household use.

**REMEMBER
Hilton's Insoluble Cement**

Is in liquid form and as easily applied as paste.

Hilton's Insoluble Cement

Is insoluble in water or oil.

Hilton's Insoluble Cement

Adheres oily substances.

Supplied in Family or Manufacturers' Packages from 2 ounces to 100 lbs.

HILTON BROS. & CO.,
PROPRIETORS,
PROVIDENCE, R. I.

Life Insurance.

THE MANHATTAN LIFE INS. CO.

OF NEW-YORK, No. 31 NASSAU-ST.

Accumulation \$1,500,000.
Claims paid \$30,000.
Dividends 700,000.

The greatly superior advantages of this old established Company, can be ascertained free of expense at any of the agencies, or by writing to the home office for a prospectus.

J. L. HALSEY, Asst. Sec'y. **HENRY STOKES, President.**
S. N. STEBBINS, Actuary. **C. Y. WEMPLE, Secretary.**

Mode of applying **JOHNS & CROSLY'S
GUTTA PERCHA CEMENT ROOFING.**

This Roofing is Fire and Water Proof, and can be applied by any ordinary laborer. It costs only about one-third as much as tin, and is more durable.

GUTTA PERCHA CEMENT PAINT

applied to leaky roofs of all kinds, will render them perfectly water-tight. It is put up ready prepared for use and for shipment to all parts of the country.

These materials have been tested on more than twelve thousand roofs during the past six years, and we can give abundant proof of all we claim for them. Full descriptive circulars and any required information furnished by the

JOHNS & CROSLY MANUFACTURING CO.,
35 William-st., cor. Liberty, New-York.

\$—SOMETHING NEW! AGENTS WANTED.

Our New "FANCY CARD THERMOMETERS"—"HEMLOCK AND SHIELD" for hand sewing—"Improved Indelible Pencil" for marking linen. "Flexible Shawl and Nursery Safety Pin," "Patent Hair Crimpers," and 19 more NOVEL, USEFUL and INDISPENSABLE articles, are warranted to give satisfaction. —Samples 25c. each. For circulars and terms address
RICE & CO., 37 Park Row, N. Y.

THE HOUSEHOLD BOON.—Dodge's

Vermil Exterminator and Bed Bug Riddance, kills "in one minute" all vermin infesting man and animals, yet so harmless to the person that infants may be safely bathed in it: a purely vegetable liquid without oil, opium, larkspur, sulphur, mercury or other injurious substances.

GODFREY, 831 Broadway, New-York.

UNIVERSAL CLOTHES WRINGER.

This popular machine sells rapidly wherever offered.

Every Family will have one!

It is only a question of time. Thousands of families every month are being relieved in the hardest of all housework, WASHING. Thousands of dollars are daily saved by pressing the water and dirt out of the clothes, instead of twisting and wrenching the fabric, and destroying the garments.

Cotton is Expensive,
Save it by using the Universal Clothes Wringer.

"Time is Money."

ORANGE JUDD, Esq., of the American Agriculturist, says: "A child can readily wring out a tubful of clothes in a few minutes." Therefore use the U. C. W., and save time and money.

Ladies who have long used them and know their value, speak in the highest terms in their praise. One says—"I would as soon be without my cow, as without my wringer." Another, "I can now go to bed and sleep after washing-day." Another, "I had to pay fifty cents for a washwoman before, and now we do it ourselves." Another, "The rich may afford to do without them, but I could not." &c., &c. These are but a few among thousands. Every one using them will report likewise.

We have seven sizes, from \$5 to \$30. Those suitable for ordinary family use, are No. 1, \$10, and No. 2, \$7. These have

COG-WHEELS,

and are WARRANTED in every particular. This means especially, that after a few months' use, the lower roll

WILL NOT TWIST ON THE SHAFT,

and tear the clothing, as is the case with our No. 3 (\$5), and other wringers without Cog-Wheels.

In April's sales of over 5,000, only 27 were of the No. 3, \$5, size, without Cogs. In our retail sales we have not sold one in over a year! This shows which style is appreciated by the public. This is the only wringer with the

PATENT COG-WHEEL REGULATOR,

and though other wringer makers are licensed to use our rubber rolls, yet NONE ARE EVER LICENSED to use the Cog-Wheels. Therefore, for cheapness and durability, buy only the

Universal Clothes Wringer.

On receipt of the price, from places where no one is selling, we will send the U. C. W., FREE OF EXPENSE. What we especially want is a good

CANVASSEUR

in every town. We offer liberal inducements, and guarantee the exclusive sale. Apply at once to
R. C. BROWNING,
347 Broadway, New-York.

TO FARMERS.

Bone Tafeu. Bone Tafeu.

MANUFACTURED BY THE LODI MANUFACTURING CO.

The large sale of this manure, and constantly increasing demand has induced the Company to arrange for its manufacture on an extensive scale.

It is composed of FINE RAW BONE and NIGHT SOIL, free from all impurities, dried and ground to a fine powder, making it quick in its action, as well as permanent in its results.

For Buckwheat, Turnips and Winter Grain, no manure can be found of equal value for the amount invested.

It is put in new Barrels, 200 lbs. in each. One and a half barrels will manure an acre.

Price, free of cartage, \$4.50 per Barrel.

All orders, which will hereafter be filled promptly, must be directed to the
LODI MANUFACTURING CO.,
66 Cortlandt-st., New-York.

TO FARMERS AND OTHERS.

We are manufacturing a Genuine Article of FINE, MEDIUM, and COARSE BONE DUST, and RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash.
Address **A. LISTER & BRO.,**
Newark, N. J.

CLUBS Can at any time be increased, by remitting for each addition the price paid by the original members, if the subscriptions all date at the same starting point. The back numbers will of course be sent to added names.

SEE HERE!

A Special Bounty

To

"NEW RECRUITS."

We want a large number of new readers to see, and get acquainted with the *Agriculturist* before January, for those who do so will generally bring along other new readers to begin with the next volume. As a special bounty or inducement, we make the following offers:

Every new name arriving on and after September 1st, will be at once entered on our books to the end of 1864, and receive not only volume 23 complete, but also the remaining numbers published this year—all for a single year's subscription, if the name is distinctly stated to be a new one, as noted below,)—Thus:*

1 *New Subscribers for 1864, received during September, will get the paper for October, November, and December, of this year, FREE.*

2 *Those received during October, will get the November and December numbers, of this year, FREE.*

3 *Those received during Nov. will get December FREE.*

N. B.—The above offers extend to all new subscribers, whether they are received singly, or in clubs, or on premium lists, or from Agricultural Societies, or otherwise.

*N. B.—Since many old subscribers are renewing in advance, it is important that new subscribers' names be marked as "NEW" when sent in, if the extra numbers are desired, for we shall not send these extra numbers unless they are specially and definitely asked for.

GOOD PAY is offered to those who collect Clubs of Subscribers. See page 281. This is a good time to get them; the above "Special Bounty," and the Strawberry Premium, will aid canvassing now. See next item.

THE GREAT STRAWBERRY is for all Subscribers for 1864, who apply in accordance with terms. Read the terms carefully through, on page 259. No distinction made between old and new subscribers.

To Wm. P.—and Many Others.—

A letter before us, from Wm. P.—, encloses 10 cents for expenses on Strawberry plants for two, but not a mark, in or upon the letter, indicates the P. O. or State, and we can not tell which one of the twenty of the same name on our books sent the letter. This is a sample of other letters on file, "waiting for something to turn up." From the usual habit of dating letters at the town only, and omitting the State, we are often greatly bothered, and frequently unable to dispose of a letter. We have more names on our books than any other publisher in the world (we write every name—other large publishers write only one name of a club of subscribers on the package of papers), and of course we have more difficulty than others.—*Moral:* Always write every name plainly, give the *Post Office, County and State* of every name, and tell briefly, but plainly and fully, just what is desired.

Short Letters—Important.—Business letters should always be brief and right to the point, giving all needed particulars, and no more. The following letter is better than one occupying a page of foolscap:

"Washington, N. Y., Sept. 1st, 1863.

The enclosed \$1.05 is for the *Agriculturist* for 1864, (and Strawberry) to be sent to George Washington, at Washington P. O., Dutchess Co., N. Y. He is a new subscriber and want the extra numbers. JOHN FARMER. To Orange Judd, N. Y. City."

If more money and names are enclosed, state definitely just what is desired, particularizing the new and old names, and what each wants. Though a name be a familiar one, we may not remember just where to find it among 75,000 others; so please NEVER forget to give Post Office and State. Seal the letter tightly, and address it on the outside plainly to: Orange Judd, New-York City.

Subscription Receipts not Given.—

It is utterly impracticable to return receipts for all subscriptions. Every paper is stopped when the time is up, so that its continued reception is an acknowledgement of payment. If any one in forwarding a subscription, specially desires a receipt, he will please enclose a

post-paid envelope directed to himself, and the receipt will be forwarded at the time of opening his letter. We try to keep our paper at a low price, by economy in time and every other item. A few cents worth of time and postage would more than consume all of the small profit there is on any single subscription for a year.

Subscription Price not Advanced.

Is the reader aware that the subscription price of the *Agriculturist* is lower than that of any other journal in the world, if we take into account the quality of the paper, its size, the number of engravings, and especially the amount of condensed, carefully prepared articles and items it contains? The great variety of crops for the field, orchard, and garden, the infinite number of plants, vegetables, fruits, and flowers, the diversity of soils and of climate, the different kinds of animals and implements, the labors of the household, etc., etc., require an amount of work, care, and research, little dreamed of by those who merely read the condensed results of editorial labor. The editorial expenses of the *Agriculturist* are equalled by no other Monthly, and by few if any of the Weekly Journals. It is only by means of an immense subscription list, and a liberal advertising patronage, that we can keep the price so low.—Thanks to the friends of the *Agriculturist* who have helped enlarge the circulation so greatly, that our receipts have kept pace with expenses during this hard year, when printing paper, labor, indeed everything connected with publishing, is so much higher than formerly. We bespeak a continuance of the same good will on the part of our present readers. Every one can doubtless add another name or two, by speaking a word to his friends and neighbors in behalf of the paper. Now is a good time for them to subscribe. (See the extra copies offered to "New Recruits.")

We enjoy publishing a paper so cheaply as to place it within the reach of the million, and shall spare no effort to keep the terms of the paper down to the same low figures as for nearly 22 years past, though its increased value is really cheapening the price from year to year. We mean to keep on lowering the terms, by making the paper better, and better still, for the same money.

Postage on the Agriculturist is only 3 cents per quarter, if paid in advance by the recipient. The old dispute about the weight, is settled by the new law which allows 4 ounces instead of 3; no copy weighs 4 ounces in any case. Any postmaster who insists upon charging more than 1 cent per number, when paid quarterly or yearly in advance, is either too ignorant to hold office, or is guilty of extortion. We ask the name of any one who hereafter exacts more than the above amount of postage, as has been illegally done hitherto, in some cases. The new law is too plain to admit of doubt.

Specimens or Extra Numbers are costly, and each copy requires two cents postage paid in advance. So they cannot be scattered around very freely. When needed for canvassing, the judgment of the applicant will in each case decide whether both the paper and the postage should be at the expense of the Publisher. Except when to be used solely for our benefit, the postage at least should be provided for.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE,

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 12 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only three cents a quarter, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New-York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
{ For Contents, Terms, etc., see page 320.

VOLUME XXII—No. 10.

NEW-YORK, OCTOBER, 1863.

NEW SERIES—No. 201.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

The glory of the year is at its height. There is a gorgeous display of color in the woods, which beautifully contrasts with the sombre hue of the cleared fields, though it is the hectic flush that betokens the completion of the decay which is already marring the landscape. The sun looks askant upon the changing scene, and is slowly transferring his favors to other lands; the birds, like gay courtiers, follow to enjoy his smiles; the hum of insects is no longer heard, they have sought safe quarters for their winter repose; a gentle haze fills the air, and all things inspire thoughtfulness. The reflections of the husbandman will naturally turn to a survey of the year's operations. In the main, the season has been one of average fruitfulness, though some complain of a late Spring and a too fervid Summer. The drouth, and the August frost completed the failure threatened in the early months. In some sections this was undoubtedly unavoidable. Human skill cannot make up for all deficiencies of weather. There will always be some contingencies depending on this cause, and these should be taken into account in estimating for future operations on the farm; a wide margin should be left on this score, when operations are contemplated requiring the outlay of large capital. He is an unskillful cultivator who depends entirely upon favorable seasons for making farming profitable. He is at the mercy of the elements, and will often have reason to complain of their inclemency. It is equally unwise to conduct agricultural operations with reference only to a single year or a short term of years. The successful man looks into the future, and lays his plans to make his land increasingly productive. He who merely strives to realize the largest returns, year by year, without keeping the future in view, may be

selling the fertility of his land piece-meal, which is in reality parting with his capital for what should be the basis of a large interest on that capital. The end of such management must ultimately be failure.—There is no operation upon the farm more fully justified than draining, in view of its immediate and permanent benefits. A thoroughly-drained field, though not independent of the weather, is provided with a regulating apparatus that will enable it to successfully withstand extremes which would destroy crops on undrained land. If the season be wet, there is a ready outlet for the surplus water; if drouth parches the surface, then the air permeating the cooler soil, leaves a supply of moisture for the wants of the growing plants. The atmosphere also contains elements needed for the building up of vegetable structure, and when the water has been drawn off, these find ready access to the roots. By the same means, deeper layers of earth are acted upon and prepared to furnish nutriment to the fibres, which will soon penetrate a soil thus fitted for their nourishment. Happily these views are no mere theories. They have been sustained by the most extended experiments in our own and in foreign countries. The English are so fully convinced of the benefits of draining, that it has been made a subject for legislation, and Government wisely aids those desirous of improving their estates, by loans on the most favorable terms. Most of our adult readers can remember when drain-tiles were first introduced in this country, as necessary to the best cultivation, and now there are thousands of acres made more productive by their use, and large manufactories, though working continually to supply the demand for tiles, are unable to keep up with the calls for them, and new parties are embarking in the business. We predict that in twenty years, or less, he will be generally considered an antiquated farmer, who has not introduced this improvement. The time may seem short, but we are a fast people, and are universally considered to be bent on "running things into the ground." The present is a favorable time for commencing or continuing this work. We counsel, as we have previously done repeatedly in the columns of the *Agriculturist*, that the work be begun, at least on a small scale, and there is little fear but that the results will so commend the operation that it will soon be very greatly extended.

Work for the Farm, Household, etc.

Take time by the forelock this month. But little growth will now be made by any summer crops, and without seasonable attention, some of them may be destroyed or injured by frost. In addition to gathering the corn, sorghum, roots, etc., preparations may be needed for safely storing them. To save a crop often requires as much forethought as to raise it. There should be a general clearing up before

the weather becomes inclement. The stable and cellars should be put in readiness, manure drawn out from the yards, ripened weeds gathered and burned, stock looked over and the surplus disposed of, tools safely housed, and everything made snug: then, when the blast comes whistling from the North, the farmer will be prepared to answer it with a cheerful whistle from within doors, surrounded with comfort and rejoicing in the sense of security.

Beans.—Thresh out as soon as sufficiently cured, and preserve the stalks for feeding to sheep or horses, for which they are good fodder.

Buildings will soon be subject to searching winds and driving storms, which will find entrance through all neglected crevices: one dollar's worth of lumber used in making them weather-proof will save many dollars in fuel and feed. See that eaves-troughs and leaders are free from leaves or other obstructions, and drains in order to carry off water. Apply paint where needed. If manure is to be thrown out of stable windows, build a shield of boards to keep it from contact with the sills and sides of the building and thus prevent their decay.

Butter.—Increase the quantity and quality by feeding the cows with pumpkins, surplus cabbage leaves, beet, carrot, and turnip tops, etc, as the pastures fail. Pack a full supply for winter use. If properly made, thoroughly worked, and stored with care, butter made now will command an extra price before Spring.

Cabbages.—Secure the late crop before injured by frost. Lay head downward in trenches, with rails at the bottom to keep them from the ground, cover with straw and then with earth, laid up in wedge shape and packed smooth, to shed rain. Feed out the surplus leaves.

Cattle.—Commence to feed with stalks or other fodder before the pastures are entirely bare. Grass partially nipped by frost loses much of its nutritive qualities, and will not fully supply their wants. Commence stall-feeding early. Provide shelter before the inclement season commences.

Cellars.—Prepare against freezing weather by banking up, if needed, but allow proper ventilation. Cement floors are neat, and will aid in preventing dampness and excluding vermin.

Carrots.—Harvest early and store in the barn, cellar, or other secure place, for feeding to stock in Winter. The tops, if in good order, are excellent for milch cows or other cattle.

Corn.—Cut up, bind, and stook for husking, or husk at once in the field, if it be not an object to save the fodder. See article on page 304.

Exhibitions.—Many of these are yet to be held, as will be seen by reference to the list published in another column. Strive to make that of your own vicinity one of the most successful. Those who might contribute on such

occasions, but who do not, are responsible for the failures of which they are the first to complain.

Farmers' Clubs.—Organize them early. One should be in operation in every school district. Secure an occasional address on agricultural subjects from competent speakers, but devote the meetings mainly to informal conversations on the facts connected with the every-day farm experience and observations of the different members: this will be of greater benefit in eliciting thought, and more interesting to the participants, than attempts at speech making, or listening to elaborate essays.

Grain.—Have all threshed and safely stored, ready to take advantage of a favorable market. Reduce all contracts for future delivery to writing, and ascertain the responsibility of parties before closing a bargain. *Cash* is the safest paymaster, the world over.

Hogs.—Push on fattening rapidly, before cold weather tithes the fat. Keep pens well supplied with pure water, and with plenty of leaves, weeds, straw, muck, etc., for making manure.

Ice-Houses may be made cheaply, and they will abundantly repay their cost, especially on dairy farms. A double-walled room with the interstices filled with sawdust or spent tan-bark, built in one corner of an out-house, provided with drainage and ventilation, are all the essentials.

Implements.—Have them all in their places under cover. Preserve iron and steel from rusting by thinly coating them over with a cheap mixture of lard and rosin melted together.

In-door Employments.—First secure all the labor-saving items for the household department, which may have long been waiting for a convenient time; such as a few hooks, pins or nails for hanging clothing, catches for loose doors, huttons or other fastenings for windows, convenient arrangement for water, scrapers for the doors, sharp knives and scissors, and all the hundred and one little matters which the women folks will think of, and which will contribute greatly to their good nature, and thus to the comfort of the household. A friend at hand proposes to the ladies, that they keep a slate or scrap of paper hanging in plain sight, and on it write a list of such needed improvements as they happen to want from time to time. It might be headed "Gentle Hints."

Manures.—In most sections a large addition can be made to the manure heap, by collecting leaves from the forest. They are excellent material to compost with cattle droppings for manure for the garden and fruit-yard. Provide sheds for the reception of the manure as it accumulates: it will be worth at least 25 per cent. more than if left exposed to the weather during the Winter. Secure a stock of lime and plaster to be used in making compost, and have an abundant supply of muck or black earth on hand for the same purpose.

Plow deeply heavy land that is intended for corn next year, and leave it exposed in ridges. The frost will pulverize the lumps and otherwise prepare it for working in Spring.

Potatoes.—Harvest and store immediately in a dark, cool, and well-ventilated cellar. A liberal amount of earth collected with them is rather beneficial than otherwise, in their preservation.

Poultry.—Provide warm, well-ventilated, and comfortable winter quarters. Keep their premises clean: occasionally pass their roosting poles through fire, to destroy vermin. Supply them with animal food as well as grain, and with plenty of clean water, gravel, and ashes to wallow in.

Pumpkins.—Store those wanted for family use in a dry, cool place, protected from frost. They may also be pared, sliced, and dried, or stewed and dried upon plates. Prepared in this way they will keep good a year or more. Remove the seeds from those fed to milch cows.

Root Crops.—Gather and store in cellars or pits out of doors before endangered by frost, commencing with carrots and ending with turnips, which are not injured by slight frosts.

Schools.—See that school-houses are in good order, and use every endeavor to secure first-class teachers. Arrange the work so that the boys may begin attendance at the commencement, to secure the advantage of early classification and of the additional time. Frequently examine as to their progress, but be in no haste to listen to "children's tales out of school."

Sheep.—Keep sheep and rams separate until five months before lambs are wanted. Keep all in good condition by occasional allowance of oats, if needed.

Sorghum.—Strip off leaves a few days before cutting the stalks. Cut off the two upper joints with seed, as soon as ripe, or before heavy frost, and cut stalks just above lower joint at the same time. Keep from freezing, and manufacture as rapidly as possible.

Orchard and Nursery.

October is a busy month in this department. Besides gathering the fruit in the established orchard, new plantings are to be made, and this causes demands upon the nurseryman and creates activity in his business. As far as we have noticed, the wood of nursery trees has made a good growth this season, and ripened well, and as soon as the leaves fall, transplanting may be done. In any soil fit for an orchard at all, Fall planting can be successfully practised. The earlier it is done after the fall of the leaf, the better, as the earth settles around the roots, and the tree becomes well established before Winter sets in. The success of planting trees at any time depends mainly on two things: the faithfulness of the nurseryman who furnishes the trees, and on that of the purchaser who plants them. Many failures result from the careless treatment of well grown and carefully taken up trees; other failures come from the careless manner in which the trees are treated in the nursery; they are so mutilated that no after care on the part of the purchaser will ever make healthy trees of them. In taking up trees in the nursery, care should be used to preserve the fibrous roots. It is very easy to take a sharp spade and cut around within a foot or so of the tree and then pry it out with its mutilated roots. To take up a tree properly, requires both time and labor. The surface soil should be carefully removed so as to expose the main branches of the roots and then each of these should be followed out and carefully lifted with all the attached fibres. In nurseries it is customary to take up a stock of those kinds which are most called for, and to heel them in, in a convenient place, so that orders may be readily filled. In doing this, too much care can not be exercised in keeping the varieties distinct. A nurseryman who has a proper appreciation of his business, will no sooner send out a wrongly named tree than he would steal its value from the pocket of the purchaser. In the nursery every preparation should have been made for the Fall trade—stakes, labels, moss, straw, bagging, twine and all packing materials should be at hand, so that all orders may be filled at the earliest possible moment.

We have so often advised farmers to plant trees that the counsel seems trite. Yet we know that it can not be too frequently repeated, and we know that no better investment can be made than in a judicious purchase of fruit trees. Every farmer should have a good orchard to supply fruit for home use, and for marketing. Any one wishing to purchase a farm will pay much more for one with a well established orchard, than he would for a place without fruit trees. Our advice has always been, to deal directly with the nurserymen and avoid tree peddlers. There are but few persons who are not within reach of a reliable nurseryman, and those who are not acquainted with one, can consult our advertising columns.

Apples.—These should be picked with the precautions mentioned in the article on marketing fruit on page 304. The later sorts may be left on the trees until frosts occur. Pick in dry weather.

Buds inserted last month will need looking after, and the bandages should be loosened if too tight.

Grounds for Fall or Spring planting may be manured and plowed, and if the land is at all inclined to be wet, abundant drains should be laid.

Insects.—Those which make their cocoons upon the branches, may be readily discovered after the leaves have fallen. Remove them wherever found.

Labels.—See that those which are partly effaced are renewed before winter. Do not depend upon labels for an orchard. As soon as the trees are planted, make a map and record the name of each tree in its proper position. See label on page 305.

Manure.—Apply to the orchard. Do not be content with putting a small quantity around the trunks, but coat over the whole surface.

Ornamental and Shade Trees.—The deciduous varieties may be planted as soon as the leaves fall.

Stone Fruits.—Cherries and Plum trees may be set out in the Fall, but the more tender Peach, Apricot, and Nectarine, are better left until Spring.

Seed Beds may be made according to hints on page 305. The same treatment may be pursued with the seeds and nuts of most of our ornamental trees.

Weeds should be kept down in the nursery until frost renders the use of the hoe unnecessary.

Kitchen Garden.

The near approach of frost makes this a busy month in the Kitchen Garden, as there are many crops which must be secured before they are injured by it. This, with preparation for next Spring's work, will keep all hands fully occupied until the ground becomes frozen. A good gardener will have everything cleared up, and the garden as clean and tidy in the Fall as at any other season.

Artichokes.—These, in this latitude, need a winter covering of litter, and to be hanked up with earth.

Asparagus.—Cut down the stalks and burn them. Cover the beds with a generous coating of coarse stable manure. New beds may be made now; hints upon this subject are given on another page.

Beans.—Limbs are ruined by a slight frost. As soon as there is any danger, pick the crop and shell and dry those not wanted for immediate use. House the poles for another season.

Beets.—These should be harvested before hard freezing. In cutting the tops, do not cut too close. Store in bins and cover them with sand or earth to prevent wilting, or if the quantity is small, they may be put in barrels. They should be allowed to dry a little before housing.

Cabbages.—Harvest upon the appearance of hard frosts. The best plan we have tried for wintering them is, to place two rails side by side, or to plow a deep furrow and set the cabbages heads downwards on the rails or along the furrow. Then by means of a spade or by turning up the earth with a plow, completely cover the cabbages, and pat the earth down hard with a spade so as to shed water. The ridges should be made on a sloping piece of ground from which water will run freely. Plants sown last month for wintering, may be set out in cold frames.

Cauliflowers.—Those which have not headed, should be taken up with a ball of earth and placed in the cellar; they will generally form heads. Set young plants in cold frames.

Carrots.—Harvest as above directed for beets.

Celery.—Harvest before severe frost. Take up the plants, and having removed the waste leaves, stack it upright in a narrow bed, and cover with earth and a protection of boards.

Cold Frames should be in readiness before the weather becomes too cool. Cabbages, Cauliflowers, etc., may be wintered in them, to afford early plants in Spring. Air should be given during mild weather. Bank earth around the frame upon the approach of Winter, and cover the glass with boards or other protection.

Hot-Beds.—Provide a heap of rich earth in a convenient place for use in hot-beds in early Spring.

Lettuce.—Transplant to cold frames. Seed may be sown in frames.

Onions.—Those sown late, for wintering over, need a good covering of litter to protect them.

Parsnips.—The main crop is to be left in the ground. A supply for use while the earth is frozen, may be taken up and buried in sand in the cellar.

Pickles.—Continue to salt cucumbers, unripe tomatoes, green peppers, melons, etc., for pickles.

Rhubarb.—New beds may be made at any time before the ground is frozen. Give plenty of manure and set the plants 3 or 4 feet each way. See directions in April Calendar.

Salsify requires the same treatment as parsnips.

Spinach.—Thin out if needed, and give a light covering of litter to protect it during the Winter.

Squashes.—A very moderate frost injures them; house in good season, and be careful not to bruise them. Any unripe Hubbards may be used at once as they are better when green than most other squashes are when ripe.

Sweet Potatoes.—Dig as soon as the tops are killed. Handle carefully; pack in very dry sand, or in cut straw; keep in a warm place. See April Agr.

Tomatoes.—Bottle or can a good supply. The frost can be kept from the vines by a light awning of cloth and the period of fruiting be thus extended.

Trenching may be done this month, and the ground thus be made partially ready for Spring.

Turnips.—The early varieties may be stored or marketed. Rutabagas and other late sorts will continue to grow for some time yet.

Winter Cherries.—Collect as they ripen and make into preserves, or keep them with the husks on to be used as needed.

Fruit Garden.

Much can be done in preparing land and in setting out hardy trees and shrubs.

Blackberries.—These can be successfully planted in the Fall. The ground needs to be enriched with vegetable matter, such as muck or leaf compost and well rotted manure. The New Rochelle and Dorchester are the best accessible kinds. We have known the finer varieties of the wild bushes to be cultivated with good results. The tall kinds should be set in rows 8 feet apart and 4 feet in the row.

Currants and Gooseberries.—Set out established plants the last of the month, and make cuttings for both as directed in the article on currants, page 306.

Grapes.—These should all be picked before hard frost. Grapes have been kept well until Spring by packing in boxes a foot square and 6 inches deep, with paper between each layer. The boxes should be kept in a cool cellar. Transplanting may be done this month. In the far northern localities the vines may be pruned and laid down this month.

Strawberries.—Beds may still be made, though it should have preferably been done last month. Cover both new and old beds before hard freezing. Forest leaves makes an excellent covering, but straw is generally used, because more available.

Flower Garden and Lawn.

Tender plants which yet remain out should be removed to winter quarters. The borders should still be attractive with late-blooming plants, and they ought to be subject to the same care in keeping as at any other season.

Bedding Plants.—Petunias, lantanas, geraniums, etc., usually get so overgrown and misshapen during the Summer that they are seldom worth taking up in the Fall. It is much more satisfactory to start new plants. If this has not already been done, cuttings should be made at once.

Bulbs.—Plant for Spring as directed last month.

Chrysanthemums.—There should be a fine stock of these, as they add much to the fall decoration

of the garden. They bloom even after hard frosts. Keep them neatly tied up.

Dahlias.—All should be properly labelled while the flowers are perfect and you are able to identify them. Do not be in a hurry to take up the roots as soon as the tops are killed: they keep better if allowed to ripen a week or two in the ground. Lift the roots on a dry day: let them dry awhile in the sun, and then pack away in a dry, cool cellar.

Frames and Pits should be ready to receive the plants. Tender roses, verbenas, salvias, geraniums, etc., may be wintered in them. Give ventilation whenever there is no danger of frost.

Gladiolus.—Treat as directed above for dahlias.

Perennials.—Phloxes and others may be divided and reset as soon as vegetation ceases. Sow seeds of Hollyhock and Wall-Flower early this month.

Seeds.—Continue to save from the best flowers until the plants are killed.

Shrubs.—Plant freely of the hardy sorts. These mostly do best when planted in the Fall.

Lawn.—New lawns may be made sowing early and rolling well, and again before Winter sets in.

Green and Hot-Houses.

The plants should all be in their places this month, the pots cleaned from weeds and moss, and the plants properly pruned and arranged according to their necessities for light and heat. A little fire heat will be needed by the tropical kinds.

Ventilation should be carefully attended to, and a proper degree of humidity kept up, by syringing.

The war upon insects must be commenced as soon as the plants are housed: they are much easier kept in subjection if taken in time.

If there is room for a few pots of annuals the seed may be sown now. They will add much to the decoration of the house in Midwinter.

Apiary in October.

Prepared by M. Quinby—By Request.

Consumers of honey look for its plentiful arrival in market this month. As they are willing to pay well for the good appearance of the article, pains should be taken to have it neatly put up, and in salable order. With a damp cloth wipe off from the boxes any honey that may have leaked out. Paste fine clean paper or muslin over the bottoms, to exclude insects and dust. Turn the boxes bottom upward to ride to market, as the combs are less liable to be broken. Pack the small boxes in a larger one that can be easily handled, and secure from sliding about and from rough usage, that the combs may be kept whole. The cells in the store combs of the boxes are usually much longer than those for breeding, and at the same time are inclined upward, as philosophy would teach us that they should be, to keep the honey from running out. If boxes with such cells, are turned bottom upward, the cells incline downward, and some honey must run out of all not sealed, and will flow over the caps of those that are covered. If inverted immediately on taking the box from the hive, while the honey is warm, it is worse than after getting cold. If the honey does not burst off caps, it will press fine particles through the pores, presenting a wet, or greasy appearance. When the honey does not come through, simply pressing against the sealing gives it a different appearance from the clear white of the best honey, when first taken from the hive, for except in large cells, bees seal these cells, without the covering touching the honey. If we care for the appearance of the honey, the boxes should not be inverted at any time, (except to prevent breaking combs when on the road.) In taking the box from the hive, it should not be wrenched off by taking hold of the top, but carefully lifted by a strong knife slipped under the bottom. It should then be set on its side or end, keeping the combs vertical until the bees are out; when put away it should stand in the same position as on the hive. The half cells next the glass, when

filled with honey—and in good seasons they will be so—if the box is removed by wrenching, will be quite apt to leak. Although we can with care usually prevent leaking, it will inevitably occur sometimes. The fine appearance of the combs may be restored with proper care. Set the box on the hive, and allow a few bees to enter, they immediately lick up all honey that is running, and that which is in unsealed cells. The danger is, in letting in too many bees, if they do not find honey running sufficient to satisfy them, they do not hesitate to bite away the caps of that sealed. As soon as the bees have cleaned all the combs, the box is to be put where the bees will leave it, as at first. Now is the time to select stocks for wintering. Those who keep none but the best, will have what is called "good luck." Too much honey in a hive is as objectionable as too little. Too many bees are not wanted. From 25 to 40 pounds of bees and honey is an abundance. A cluster of bees that extends through seven or eight combs, on a cool morning, the latter part of this month, may be considered a reliable one, unless diseased brood, or excess of honey causes them to spread out more than usual. . . Any stocks containing foul brood should be broken up at once. If the brood be not all hatched by the middle or last of October, something unfavorable may be suspected. . . Some failures must be looked for in attempting to winter hives not possessing all the requisites above named. Those having sufficient bees and comb, may be fed up to the proper weight. The feed should be given to them as fast as the bees can take care of it. It is not safe to depend on the weight of the supplies given to the bees; ascertain the real condition by weighing the hives after feeding what is deemed a proper amount. If combs are deficient, bees and honey will be also. In such cases it is best to take out the bees and set the hives away in some cold room where they will be thoroughly frozen, and keep them for use another year. They should be placed right side up, and have every crevice stopped to keep out all intruders. . . Condemned colonies should be driven out before killing the bees; it is less trouble than removing them from the combs when taking the honey from the hive. Strain the honey from combs unsuitable for the table; it drains out more easily if the combs be crushed before they are cold.

N. Y. Fruit Grower's Meetings.

During the hot weather, these gatherings were partially suspended, but now that the season of fruits has come, the growers seem to have renewed their interest in the meetings, and on Thursday, Sept. 10th, a large number of them assembled and had an interesting talk, a few points of which we give below. There was a fine show of fruits, better than can be seen at some State Fairs, and more instructive too, for the fruit was tested as well as seen:

Mr. E. E. Clark, of New-Haven, called to the chair.

C. W. Idell, of West Washington Market, presented a basket of fine Crawford peaches for distribution to the members; some seedling peaches of promise were shown, one of which, the "Creole" was remarkable for its thin skin and delicious flavor.

Mr. Cole, of Conn., showed some plums, seedlings of wild Iowa plums, which, though possessing a tough skin, with rather coarse flesh, were considered worthy of attention on account of their freedom from the knot, and from the ravages of the curculio.

Dr. Ward, of Newark, N. J., stated that he went largely into the plum culture 15 years ago, planting hundreds of trees, but so completely were the crops destroyed by the curculio, that he rooted out all his trees. He thinks that by starting again with this wild plum, the skin of which is too thick for the curculio, we may improve upon it and yet raise passable plums.

Dr. Trimble said it was cowardly and disgraceful to submit to an insect enemy so easily conquered. He had seen a good collection of plums from Ellwanger & Barry, who jar the trees and thus raise a fair crop.

Dr. Newberry made a chicken yard of his plum orchard and now has fruit where it was formerly destroyed. The plan should be pursued by neighborhoods, or the insects from neglected orchards will sting others' fruit.

Dr. Trimble has heard much about the instinct of the curculio, that the female will not deposit her eggs over water, but a visit to Dr. Underhill's place where the plum

trees hang over a pond, proved that such was not the case, as the plums overhanging the water were equally affected with the others. True, the larvæ of those which fell into the water would be drowned, but the others had learned no lesson by their fate. The jarring process if followed up, will save enough plums. Hard winters and dry seasons destroy immense numbers of the curculio.

A. S. Fuller thought we might as well try to destroy mosquitoes as curculios—a few trees could be attended to, but the task would be too great with whole orchards.

A plate of Tyson pears from J. McAfee, of New-Bedford, Mass., was presented, and the fruit pronounced very fine, though rather over ripe; this is one of our best pears.

Dr. Trimble showed fine specimens of Bartlett pears for which dealers would pay \$18@20 per bbl. He thought the trees were almost destitute of fruit early in the season, but as nearly every specimen grew large and fair, they turned out well, the high price making them a profitable crop. Bartlett's sell better than any other pear; we can not change public opinion.

John Hicks of Long Island, at a previous meeting, had advocated Willis' Sweet as the best apple for baking. W. S. Carpenter set forth in equally strong terms the superiority of the Westchester Pound Sweet as a baking apple, and it was agreed that each should present at this meeting a specimen of the baked fruit. Mr. Carpenter was unable to be present, but Mr. Hicks came, bringing a dish of nicely baked Willis' Sweet apples, the quality of which was tested by the meeting, and it was agreed that the fruit for baking purposes could not be too highly recommended.

A. S. Fuller showed specimens of grapes, among which were Blood's White, very foxy and worthless; Blood's Black, which was little better; a good wild grape, Canby's August, which was a step in advance of either; and one of the earliest blue grapes, of passable quality, and which has been too much neglected; next follows the Hartford Prolific several steps in advance of the last, in point of flavor, but still a little foxy, yet sweet and good, an early and abundant bearer, and the fruit sells well. Oporto and Taylor's Bullitt had very few perfect berries on the clusters. There appears to be some radical defect in the flowers; they do not fertilize well; are always deformed, making them worthless here. Delawares were exhibited last, with these there is little except size to be desired.

G. R. Garretson of Flushing, exhibited well ripened Hartford Prolific grapes, and some Northern Muscadine, the latter a pretty good fox grape.

T. W. Field wished to bear testimony to the excellence of the Hartford Prolific, which, besides its other good qualities, bloomed so early that it escaped the ravages of the rose bug, and ripened long before any danger of frost in the Fall: it does not drop unless the vines overbear.

Fejee Tomatoes were shown by W. W. Davis. This, Prof. Thurber pronounced the tomato for cultivators. Several large market men in the vicinity of New-York, are discarding the old sorts and substituting the Fejee.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

Seventeen Thousand Neighbors are now visited by the *Agriculturist*. In each of these, one or more persons may secure valuable articles from our premium list, without cost. There is scarcely a town in the country where there are not twenty to a hundred or more families, that would find the *Agriculturist* a valuable visitor. All that is required is, for some enterprising person to present the merits of the paper and gather up and forward the names. The reader will be interested in turning to page 313 and looking through the premium list and the descriptive notes. Nearly 3000 persons secured one or more of these articles last year, and with almost universal satisfaction, as our correspondence abundantly shows. This year, ten to twenty thousand persons may each get premiums.

A Soldier's Widow Greatly Benefited at Small Cost.—Seven ladies, in planning how they might do something to assist a soldier's wife, resolved themselves into a committee and canvassed the town for subscribers to the *Agriculturist*. In two days they raised a club for a premium Sewing Machine which they presented to her, and she is now able to support herself and family. Many people subscribed to promote such an object, though they had not previously become awake to the value of the paper to themselves.

How the Agriculturist was obtained at 58 cents a year.—One hundred men subscribed a dollar each, and the club received a Premium Wheeler & Wilson's Sewing Machine. It was then put up at auction, to be bid for only by members of the club, and

was sold for \$43.50. Of this, \$1.50 was paid for freight expenses, and the remaining \$42 divided among the club, which reduced the cost of the paper to them for a year to only 58 cents each. Similar enterprises have been undertaken elsewhere with like results. An Agricultural Society in Iowa subscribed for the copies as a Society, and gave them away as premiums, and then sold the machine for the benefit of the general fund.—A good operation in both cases, and suggestive to others.

Subscription Receipts not Given.

It is utterly impracticable to return receipts for all subscriptions. Every paper is stopped when the time is up, so that its continued reception is an acknowledgment of payment. If any one in forwarding a subscription, specially desires a receipt, he will please enclose a post-paid envelope directed to himself, and the receipt will be forwarded at the time of opening his letter. We try to keep our paper at a low price, by economy in time and every other item. A few cents' worth of time and postage would more than consume all of the small profit there is on any single subscription for a whole year.

To Correspondents.

The "writing mood" often seems to depend upon the weather, or the state of the country, or something else, judging from the fact that at times we receive box full after box full of letters, on all sorts of topics, and then there is a dearth of them. In the former case we must necessarily delay early responses to some of them. Often we cannot answer the queries made, but do not take the time to write to that effect, unless there is some important reason for so doing. We are glad to receive any number of practical hints, suggestions, items of experience or observation, queries, etc., but hope none will esteem us neglectful if they do not have instant attention.

Important.—Always write every name plainly; give the *Post Office, County and State* of every name; and tell briefly, but plainly and fully, just what is desired.

Volumes of the Agriculturist, as far back as the 16th (1857), can always be supplied. Unbound at \$1 each; or if neatly bound, at \$1.50. If to go by mail, \$1.24 in numbers, or \$2 when bound.

The N. Y. State Fair is in progress, as we go to press. The telegraph reports it to be a decided success, pecuniarily at least. One of our Editors is present, to gather any noteworthy items for the next paper.

Come and See the Grapes.—This paper will reach most of our readers before the first day of the month, when the great display of Grapes is to open at the office of the *American Agriculturist*. It will doubtless be the best show of this fine fruit ever seen in this country. Our Office is so arranged that we can remove desks, screens, etc., if necessary, and thus give up the whole floor, 80 feet long and 25 feet wide, to the exhibition tables and visitors. The best part of the day for seeing, will be early in the forenoon, any time after 8 o'clock, A. M., as there will naturally be a much greater crowd in the afternoon. About 25,000 persons were present during the three days of the Strawberry Exhibition, without great inconvenience. The grape show will be open to the public, free of charge, from 2 P. M. on Thursday to 4 P. M. on Saturday—Oct. 1st, 2d and 3d.

The Cucurbitaceous Show.—All who have specimens of Pumpkins, Squashes, Gourds, remarkable for size, appearance or novelty, will be interested in the show of the cucurbitaceous family, (which includes Gourds, Pumpkins, Squashes, etc.) to open Nov. 4th, as announced in another column. We desire early notice of what is to be exhibited, in order that good provision may be made for their proper display. The exhibition last year happened at a very rainy season, but should this occur again, the specimens will bear keeping until fair weather, so that all who desire to do so can call and see them. Let us have, as far as possible, the correct name and origin of specimens, and any unusual item in the cultivation, for the interest and instruction of visitors.

The Strawberry Plants, offered as Special Premiums last Summer, are all sent out. The excessive drouth that checked the growth of good roots, delayed the forwarding of them until Sept. 14, to 21.

Frost and the Cotton Experiment.

From a friend who has recently passed through Illinois, and from a large number of correspondents, we learn that the ravages of the frost have caused many sections to present a most melancholy spectacle. The cotton is pretty generally killed outright. A great many acres were planted last Spring at a heavy expense for the seed. The hopes of those who have thought to make Illinois a cotton growing State, we are sorry to say, are disappointed, and some are large sufferers by the experiment.

Naukin or China Sheep.—J. S. M., and others. We have never discovered anything in this breed of sheep to recommend them over others, except their prolificness, and this is probably offset by lack of vigor of constitution. They have been in the country some six or eight years, and have not been as much disseminated as one would expect, if as really valuable as claimed.

Caked Bag.—Mrs. E. C. Wheeler, of Essex Co., N. J., says, take $\frac{1}{2}$ lb. of the green bark of the Bitter-Sweet (*Solanum dulcamara*), steep it in sufficient water to make a strong tea, drain off the liquid, add 1 lb. of lard to it, and let them simmer together to the consistency of lard; when cold, rub the affected parts thoroughly with the mixture, night and morning. A perfect cure will be effected in two or three days. The application has proved, upon repeated trials, equally as good for human beings as for animals.

Greasing Chickens.—Jos. Michener remarks on J. Bright's chicken-greasing: "Of course it does not do to grease sitting hens with him or any one else, simply for this reason: it fills the pores of the shell, and the chicken smothered; but as soon as all the eggs are hatched that are likely to, take the hen off and grease her as much as 'he or any one else' wants to, and I will insure him that the lice will die, and the chickens will live."

Husking Aids.—J. Seofield, Windham Co., Conn. Among the many contrivances to lessen the laborious operation of husking corn, we know of nothing better than the "husking pin," described in the *Agriculturist*, Vol. XX, p. 9, (Jan. No.), which may be of hickory, bone, or iron. It is held in the palm of the hand by a leather strap passing over the two middle fingers, and the pointed end is used instead of the thumb and finger nail, to open or part the husks.

Packing Pork.—A subscriber wishes to know the best method of salting pork; whether saltpetre is necessary for its preservation, and whether it is advisable to repack it in the Spring; also whether there is any reliable method of cleansing tainted barrels. Will some one having successful experience please contribute his method, and also answer the other queries named above.

Killing Quack or Quitch Grass.—S. K. Walkup, of Framingham, writes that he succeeds in destroying this pest by smothering it with old straw, hay, or other mulch. He covers it in the month of June, and succeeds in killing out the plant in about a month.

Rats Again.—Isaac Hicks, of Queens Co., L. I., says that being much troubled by rats, he dropped some chloride of lime into their holes, and the rats have not been seen or heard of since.

Deep Plowing for Potatoes.—A Long Island subscriber, M. Foley of Suffolk Co., placed some very fine Peach Blow potatoes upon our exhibition tables, with the remark that deep tillage and thorough working of the soil gave such potatoes, while those of his neighbors, on lightly stirred ground, with little tending, were literally "burned up" by the drouth. If deep tillage is good for the light soil of Long Island, still more will it benefit the heavier soils of the main land.

Large Egg Plants.—The purple egg plant, under skillful culture, frequently grows to a very large size. Several specimens on *American Agriculturist* Exhibition Tables weigh five and six pounds each. Among those shown by Wm. Simpson, of Westchester Co., N. Y., one weighs seven and one half pounds, but that yields the palm to a mammoth specimen grown by R. M. McGarretty of the same County, which measures 29 $\frac{1}{2}$ inches in circumference and weighs eight pounds and ten ounces!—The largest we have ever seen.

Ripening Tomatoes.—J. Hussey, York Co., Me. As there are frequently a few nights of frost in your vicinity, followed by warm weather, you can easily protect the unripe tomatoes with mats, quilts, horse blankets, etc., in threatening weather. A little care for two or three nights may keep them ripening for weeks. Or the plants may be taken up with earth around the roots, and set in a shed or cellar to ripen the fruit.

Crab Apples.—J. W. Decker, Wayne Co., Pa. The red crab apples sent are very handsome, of large size and of good flavor. Considerable attention has lately been paid to the Siberian crab, and several seedlings of promise have been sent out. One variety called the "Hyslop crab," brought in by H. A. Conger, Walworth Co., Wis., measures 5 $\frac{1}{2}$ inches in circumference, is of a bright red color, covered with a rich bloom, and is

of fair flavor. The Crab Apple merits attention as a thrifty growing tree, ornamental in foliage, and flowers. The fruit, besides being beautiful, is valuable for preserving.

Profitable Pears.—To-day (Sept. 11th), we have seen good Bartlett pears selling in Washington Market, New-York City, for \$15 to \$18 per barrel, wholesale, and the dealer informed us that choice selected Bartletts would bring from \$18 to \$25 per barrel. Half a dozen large well grown trees would yield more profit than a whole acre of grain or other field crops, and perhaps more than an acre of apple trees of the same age.

Unripe Grapes.—Grapes are usually picked before they are fully ripe. We have heard persons call the Isabella a poor, sour grape, simply because they commenced picking as soon as the fruit began to color, and the grapes were all gone at least a week before they would have been fully ripe. The Isabellas, particularly, should remain on the vines at least one week after they appear fully ripe. When designed for keeping, leave them uncut until in danger of freezing—a light frost will not injure them.

Fall Pruning of Grape Vines.—"G. T." Yes; we like Fall pruning, and the sooner it is done after the first hard frost the better. If left until just before Winter sets in, and the weather should be cold all the time, the shoots will frequently bleed in Spring.

The Cut Leaved Blackberry Again.—S. H. Halsey, Esq., of Astoria, L. I., has brought us specimens to show that this variety is, with him at least, a good bearer. The branches hang as full as need be, and the fruit is of good size. It is sweet, but has a flavor which will probably not please some persons. The vines are disposed to run to the length of 20 or 30 feet. Mr. H. keeps his cut back to about 6 feet, and has an abundance of fruit. See August *Agriculturist*, page 231.

Planting Raspberries.—"J. H. C." As most of the cultivated sorts are only half hardy, it is better to plant out in Spring after they have been safely wintered. When set in the Fall, there is required the additional labor of covering them.

Strawberries from Seed.—Chas. A. Warren, New-Haven Co., Conn. Your seedlings probably will not bloom until the third year. The runners should be kept off, and the plants be well cultivated in order to get as strong and vigorous stools as possible.

Triomphe de Gand Strawberries Productive.—J. R. Flink, Luzerne Co., Pa., was inclined to rate this strawberry a poor bearer, after one year's trial. The plants were strong and healthy, and being set in August, he looked for a full crop the following Summer, and was disappointed; but tending them well, and keeping them in stools, the result the next season was perfectly satisfactory. No strawberry will yield a full crop the first year after setting them out in Autumn.

Small Fruits.—Mr. Knox of Pittsburg has the largest and most complete "Small Fruit" plantation in this country, if not in the world. Others may have more of one kind, but he has all the small fruits—strawberries, raspberries, grapes, etc., and a large amount of each. In passing through Pittsburg, in July, we made a hurried visit to Mr. Knox's place, a little distance southwest of the city,—not to gather any special notes at the time, for we were too much worn down with the labors at Gettysburg—but to take a general look at the whole. We were highly pleased with what we saw, and shall take pleasure in making a future visit of greater length to study the small fruits where they are so well grown, and on so large a scale.

California Wines.—California is not only a wonderful country in its mineral products, but its agricultural and horticultural resources are constantly exciting our admiration. The European vine was introduced there by the early Jesuit missionaries, but its culture did not extend much beyond the grounds of the Missions until within a few years. Now that enterprising Americans and Europeans have undertaken the culture, California bids fair to become one of the great wine-producing countries of the world. The products of her vineyards already find a place in this market.

Lilium Brownii.—This is one of the most beautiful of the Japan Lilies; we have a fine specimen of it from the grounds of A. S. Fuller, Esq., of Brooklyn. This sort is quite dear as yet, but we hope that this and the other varieties will soon be at a price which will bring them within reach of everybody.

A Pretty Variegated Plant.—John Paddock, Houston Co., Minn., sends us *Euphorbia marginata* raised from seeds from Pike's Peak. We have seen acres of it in Texas, but never saw it in cultivation. We should be glad of some seeds.

Seeds Received.—J. G. English, sends us some seeds of a White Perennial Phlox, found in the Grand Prairie, Ill. We shall make a trial of them.

Dyeing with Sumach Berries.—Mary Brown, of Rush Co., Ind., wishes to know how to color yarn with sumach berries. Who can tell her?

Take Care of the Sorghum.—Now that the crop is grown and already being worked up in some places, see to it that none goes to waste. If the crop cannot be ground and evaporated as fast as cut, stook it, either in the open field or in covered sheds—it will then keep good for weeks. It should be worked up, however, as fast as possible, grinding in a strong mill to press out all the juice. Evaporate in shallow pans as fast as ground, and no chemicals will be needed. The quicker the juice is boiled and skimmed, the clearer and lighter colored will be the syrup.

Sugar Evaporators.—As an indication of the extent to which sorghum growing is being carried on at the West, we may mention that one firm, Messrs. Blymyer, Bates & Day, of Ohio, who manufacture the Cook's Evaporator, are turning out 60 per week, and expect to dispose of 1,500 to 2,000 for the Incoming crop.

Cheap Paint.—L. T. Nells, of Hamilton Co., Ohio, sends us the following recipe for a paint which he says is of German origin. He says it wears and washes well, is water-proof, and may be used for house-floors and out-door work. The proportions for 400 square feet are: 2 $\frac{1}{2}$ oz. Beeswax, 1 oz. Potash, $\frac{3}{4}$ oz. Ochre, 1 oz. unburned Terra de Sienna, and 6 pints of water: boil for two hours and apply it hot.

Cleansing Cemented Fruit Bottles.—Lucia N. Hall, of Ashtabula Co., Ohio, writes that upon noticing the directions given on page 231, August *Agriculturist*, she tried boiling the bottles in strong soap suds, and found it effectual. To prevent breakage, the bottles should be put in before the water is hot, and taken out after it has cooled somewhat.

To Cleanse a White Cape Shawl.—A lady asks how this can be best done without danger of injuring the shawl. We do not know. Who does?

Book for Self-Instruction in Latin.—Genie Belmonte. Either Harkness' or Arnold's First Lessons will answer your purpose.

Farm Book.—"J. H. A." Westchester Co., N. Y. You will find several good books on farm topics in our list published on one of the last pages of the paper, but there is no one book which so generally meets the varied wants of the farmer, (who should also know something of flower and vegetable gardening, and also fruit-growing), as a living periodical like the *Agriculturist*, which notes, as they transpire, all the improvements, both in modes of culture and in the things cultivated.

The Natural Laws of Husbandry, by Liebig, D. Appleton & Co. Perhaps no writer has done so much to excite an interest in the science of agriculture as Liebig, and whatever comes from his pen will attract attention even from those who reject his theories. The present work contains the matured opinions of this distinguished author. Those who open it expecting to find a practical agricultural hand-book, will be disappointed. It requires a certain amount of scientific knowledge to read the work understandingly, and those who have this requisite, will find in it much food for thought. The translator has probably made it less popular than the original; thus we find Amylum used instead of starch, and sundry other unnecessary displays of learning. The American reader should bear in mind that where corn is spoken of, wheat is meant.

Heat Considered as a Mode of Motion, by John Tyndall, F. R. S., etc. N. Y., D. Appleton & Co. This is one of the works of which there are unfortunately too few—one in which the profoundest views of a most difficult subject are presented to the comprehension of any intelligent person, in a perfectly plain manner, without departing from scientific accuracy. It is a charming book on a subject of universal interest, and the Appletons have done a good service in re-publishing it in such an elegant form. We mail it for \$2,

Feed for Horses.—Robert H. Martin, Sussex Co., Del. Oats are universally considered the best grain for feeding to horses. If the straw be well cured, and the unthreshed bundles be run through a straw-cutter, the feed cannot well be surpassed. The straw so used should be free from rust, and it is considered an improvement to slightly wet the whole just before feeding.

Currycomb Substitute.—W. B. Waldo, Dutchess Co., N. Y., writes to the *Agriculturist* that a case-knife, with the edge made smooth but not sharp, is equally effective with a currycomb in removing dust and scurf skin from the horse, and pleasanter for the animal.

Garget in Cows.—S. S. Moody, Hampshire Co., Mass. This disease is the result of inflammation of the lymphatic glands of the udder of the cow. It may be produced by neglecting to draw off the milk, by external injury, fevers, etc. If neglected, matter may be formed, and a bad abscess result. In its first stages it may usually be relieved by washing the bag with warm water, and then after wiping it dry, applying to the entire surface melted lard, as hot as the animal can bear it. If abscesses be formed, they should be lanced.

Grass for Sheep.—James McCollum, Niagara Co., N. Y. The grass best suited for sheep pasture must depend on the character of the soil. Where blue grass will flourish, nothing is more suitable; in other sections we should prefer timothy, or if exposed to much drouth, should try orchard grass, which bears very close feeding, and is much relished by sheep or cattle.

Freeing Poultry from Vermin.—Edward A. Lewis, St. Charles Co., Mo., writes: "Last year my hens were so infested with vermin that they died on their nests, and even on the roosts. It was impossible for a person to step into the old hen-house, even for a moment, without bringing away colonies of the detestable insects in his clothing. Upon transferring the hens to the new building, they were all rubbed with a mixture of lard and Scotch snuff. The old house was fumigated with tobacco stems and thoroughly white-washed. *Sassafras* roosting-poles were adopted in the new house, from a suggestion found in the *Agriculturist*. To all which, together with the burning out of the nests, may be attributed the fact that there has not been the least appearance of the pests on my premises the present year.

Subsoiling.—W. C. Pierce, Clinton Co., N. Y. Subsoiling would undoubtedly benefit a clayey loam resting on a gravelly hardpan, but permanent draining with tiles would be a more lasting improvement. We can not name the best subsoil plow; several good patterns may usually be found at any agricultural warehouse. It is not necessary nor advisable to bring up the subsoil to the surface where the soil is eighteen inches to two feet deep. Driving the plow through it will open it to the action of air and moisture.

Prevention of Smut.—James R. Boyd, Ontario, Wis., writes to the *American Agriculturist*, that last Spring he sowed Scotch Fife wheat, after having washed the seed with strong salt brine and rolled it in lime until it was well covered. The crop was entirely free from smut, while neighboring fields without this application, were badly infected. We have used with success a wash of dissolved sulphate of copper (blue vitriol); perhaps common salt would be equally useful.

Orchard Grass with Clover.—William Shockley, Jr. Orchard grass sown with clover makes an excellent mixture, as the two ripen together, and the hay produced is of the first quality. It may be sown with winter grain, the same as timothy. A bushel per acre is sufficient seed when to be mixed with clover. We do not know that it would be less injurious than timothy to the wheat crop, but the experiment is worthy a trial.

Time for Plastering Clover.—James McCollum, Niagara Co., N. Y. We prefer to sow plaster upon the young growth of clover in the Spring. It then has an opportunity of expending all its virtue in forwarding the plants, before being partially washed away, as it would be if applied in Autumn.

Breaking Up Prairie Lands.—"Minnesota" desires some one practically familiar with the operation, to give in the *Agriculturist* details of his experience in breaking up prairie land, as to the best season, what is preferable for the first crop, method of cultivation and the result. He asks "Does the sod rot better when laid flat and even, than when rough and exposed to the weather?" Many now seeking homes in Southern Minnesota, Northern Iowa, Wisconsin, and other prairie

regions, would be greatly benefitted by such information from those who have "been through the mill."

Practical Questions are often as valuable, because suggestive, as direct information. E. J. Judd, Ontario Co., N. Y., sends the following for answer in the *American Agriculturist*: "What does it cost per bushel to grow corn along the line of the N. Y. Central Railroad, and what is the average product per acre? What weight of ears of the 8 and 12-rowed varieties will yield 60 lbs. of shelled corn? In the same section, what is the cost per rod, to thoroughly underdrain land, two feet deep, with good tiles of 1½ inch bore? Also, what is the experience, in these matters, of those living along the line of the N. Y. and Erie Railroad?" As these roads run through districts varying in character along their routes, some of the answers would present widely different figures; still they would contain useful information.

To Keep Bees from Over-swarming.—Several inquirers. Mr. Quinby writes on this subject for the *Agriculturist*: "With the ordinary box-hive, there seems to be no practical way to prevent over-swarming. When there are but few stocks kept, it is possible to remove the queens of the after-swarms, and return the bees to the parent hive. But in large apiaries, it is common to have several swarms issue at once, and cluster together, making it impossible to return each swarm to the hive to which it belongs. In the movable comb hive, the following management will control them: A week after the first swarm has issued, take out the combs and cut off all the queen cells but one, and the work is done. It will not answer to wait until some of the queens mature, and then do it, as by that time the bees get up the swarming fever, and they will sometimes come out with the last queen they have. Over-swarming is disastrous, even when an increase of stocks is desirable, as the old one is often ruined, and perhaps only one of the new ones suitable for winter. By a little management, two, and even three powerful colonies may be obtained from one in a single season, and not impoverish the old one at all. The queens may be reared artificially. The Italians work much better in this way than the natives, and introducing a mature one to the old stock almost immediately after the first swarm, will result in one or two additional swarms without leaving the old stock almost destitute of bees, during the season of the best yield of honey."

"Northern Honey."—Several inquirers. This is an old invention, secret recipes of which were peddled about the country several years since, at from ten dollars to twenty-five cents, according to the verandage of the customers. The directions for making it, published in a former volume of the *Agriculturist*, are as follows: Dissolve 20 lbs. of coarse sugar in 3 quarts of warm water. Stir into it one-fifth ounce of cream of tartar, first dissolved in a little water, and also five or six pounds of good honey, and half a teaspoonful of essence of peppermint. Boil the whole slowly for 12 minutes, stirring it all the time, and it will make 30 lbs. of a mixture which with some may pass for honey.

Preserving Cheese from Flies.—S. E. Ogden, Austin, Mich. New cheese should be anointed with butter or oil made from whey-cream, which rises from whey set apart for the purpose after being drawn from the curd. It is skimmed off and churned like other butter. In hot weather a sprinkling of cayenne pepper mixed with it will repel flies. A little beeswax added, hardens the mixture, and is better for the hot season.

The "Wine-Plant" Humbug.—From the frequent advertisements and notices now appearing in the newspapers, we feel constrained to again caution our readers against investing money or time in any so-called "wine-plant." Last year it was the "English wine-plant;" now there are several names. The gist of the matter is, that from the juice of any variety of rhubarb, it is possible to make an alcoholic drink, by adding sugar, and fermenting it. The same is the case with the juices of a great number of other plants and fruits. But there is no essential difference between cider whiskey or cider brandy, and the so-called "rhubarb-wine," except in the amount of alcohol, and that the latter has a different flavor. There is little if any difference in the different kinds of rhubarb, so far as their capability of producing alcohol with sugar is concerned. One of the best varieties of rhubarb for cooking or any other purpose, is the Linnæus, or "Myatt's Linnæus," as the same plant is sometimes called, from Mr. Myatt who first raised it from seed. This variety is now abundant, and has been advertised in the *American Agriculturist* the present year for \$18 per thousand roots! If anybody invests in it at \$25 per hundred (that is \$250 per 1,000!) because some speculator names it a "wine-plant," he pays

pretty dearly for neglecting to invest a dollar a year in the *Agriculturist*, in which paper the imposition was shown up some time since. We see it stated that nearly 4,000 gallons of this (rhubarb) wine is produced from one acre, and that it readily commands \$2 per gallon! *Credat Judæus!* Pray tell us what responsible party is ready to contract for the product of ten acres (35,000 to 40,000 gallons,) at a dollar a gallon.

Souring of Wine.—Benjamin F. Huntington. Wine and other fermented drinks will sour from exposure to the air. Fermentation is produced by the oxygen of the atmosphere uniting with the sugar of the juice, at first changing it to alcohol, and ultimately to vinegar if the process be continued long enough. Cork bottles or casks tightly when the first or vinous stage of fermentation is completed, and it cannot sour. The vessels should be full, otherwise enough air may be present to induce a change.

Cover the Spinach.—O. L. Allen, Berks Co., Pa. Spinach sown early in September should be covered with hay, straw, or other litter, just before the ground freezes up. A covering of an inch thick is sufficient, and the straw should be removed when danger of hard freezing is over in the Spring. Thin the plants before the covering is put on.

Black Knot on Plum and Cherry Trees.—"F. T.," Delhi, N. Y. This is not caused by an insect. It is very well explained and figured in the *Agriculturist* for April.

English Ivy.—H. P. Rogers, Fulton Co., Ill. We cannot tell whether the Ivy will flourish with you. We should try it on the northern rather than on the southern side of the wall, as it will be less exposed to alternations of heat and cold.

Magnolias in Michigan.—O. M. Wood, of the Botanic Gardens and Nurseries, Clinton Co., Mich., states that *Magnolia acuminata* grows well with him, and is as hardy as an oak, while the Catalpa is invariably killed to the ground every Winter.

American or New-Jersey Tea.—Some one in Columbia, Pa., sends us a specimen of the leaves of this plant, which was described in the September *Agriculturist*. He thinks it will never suit the palate of an old tea-drinker. There was money in the letter, but no signature. The number of the letter is 95093. The paper can not be sent unless we have the address.

Egg Plants Delicious if Cooked Rightly.—Many readers say they do not understand how others can like the egg plant. We can; cooking is everything. The best directions are given to the *American Agriculturist* by one of its housekeeping readers. Cut the plant across into thin slices, say ¼-inch thick; salt and lay these together over night; in the morning take them from the brine and sprinkle finely powdered cracker over both sides of the slices; then fry brown (not black) in just enough fat to keep them from sticking to the griddle. Some use Indian meal instead of cracker, but the cracker is best. We eat them thus cooked, and esteem them a really cheap delicacy, though we once thought them poor stuff. A subscriber at our elbow says: "Cut them into slices nearly ½ inch thick; sprinkle on salt, lay them together with a light weight on the top; in the morning drain from the brine, roll in flour and fry in butter, and they can't be beat."

Not Quite Right Yet, Mr. Humbug! One of the swindlers in Philadelphia sends out his "gift" and other enterprises, under the name of Messrs. "BANE & Co." Right so far, for the operator is a bane to society. But having exhausted his list of known names, he is now putting up envelopes, printed with a neat mechanical device, which he sends to different parts of the country, addressed: "To any mechanic, in the Town of —, County of —, State of —," and requests the Postmaster to deliver the letter to some mechanic. Enclosed and sealed up are a lot of schemes, tickets, etc., with great inducements for investing from 25 cents to \$1 or more. We suggest to Mr. Bane, that his letters would be more appropriately addressed: "TO THE GREATEST FOOL in the Town of, etc."

Pronunciation of Names.—J. M. Porter, Roxabel, Ohio. The names of the authors mentioned in your inquiry are pronounced as follows: Boussingault, *Bô-sang-go*; Brandt, *Brant*; Buist, *Bu-ist*; Chortlon, *Ch soft*, as in cheese; Goodale, *Goo'dale*; Guenon, *Gernon*, (G hard, as in get); this is the nearest approach we can give to the French sound of the u in the first syllable. Leuchar, *ch hard*, as in chasm. Liebig, *Lee-big*; Youatt, *You-ot*.

"Stuffing" Live Poultry.—C. J. Waters, Broome Co., N. Y. This is practised extensively in Europe, and by some poultry raisers in this country. Fowls are confined in close dark quarters, and their crops are frequently filled with dough forced down their throats. By this treatment they may be made excessively fat, but it is doubtful if the meat can be wholesome, as the process is clearly an unnatural one—we need not say it is cruel. Plentiful feeding with grain and sour milk will make fowls plump enough for our use, "or any other man's."

Keeping Eggs in Bran.—M. A. Humphreys, Delaware Co., Pa., communicates to the *American Agriculturist* the following method for preserving eggs, which she says has been successfully practised in the family from the days of her grandmother of the 17th century. Prepare bran by drying it in a pan in the stove, to prevent its moulding. Place a layer of this in a box or barrel, then the eggs in regular rows, points downward, and thus with bran and eggs alternately, fill the vessel. They should be kept in a dry place and free from frost.

Sulphuric Acid (Oil of Vitriol).—To several querists. This is usually put up in Carboys, that is, large, thick glass bottles, which hold about 150 pounds each. These are each set in square boxes for carriage. The present price of sulphuric acid is 2½ cents per pound, wholesale. The carboys are charged for extra, at \$1 50 @ \$1 75 each, which price is refunded if the carboys are returned empty. This is the acid used for dissolving bones for manure.

To Dry Up Milk.—Robert H. Martin, Sussex Co., Del. A strong solution of alum in brandy rubbed on the udder of an animal a few times daily, will usually check the flow of milk, and relieve the animal from danger of garget, when the young are weaned, or it is desirable, from any cause, to dry them off. The wash should be applied as warm as can be borne by the hand.

Caterpillars.—"W. G. B." of Newark, N. J., asks what he shall do with the caterpillars which are this year very abundant in his section.—We were in the neighborhood of Newark a few weeks ago, and saw large trees completely stripped of their foliage. We know of no remedy short of actual destruction. The work must begin with the season as soon as a nest is discernable.—Swabbing out the nest with some cheap oil, or removing the caterpillars by means of a spiral brush, sold for the purpose, are the usual methods of warfare.

Not Alone by Farmers is this journal taken and read, as we have abundant evidence. It is for the Household and the Garden, as well as for the Farm. Many thousands of copies are taken in this City, and in most of the villages in the country, by mechanics, professional men, tradesmen, and others. A letter before us, from interior New-York, mentions incidentally the occupation of ten subscribers, thus: 3 stone-cutters, 3 teachers, 1 blacksmith, 1 carriage-maker, 1 farmer, 1 editor.

Seeds by Mail.—A letter from the Office of the P. M. General informs us that the instructions under the new law are amended, so that packages of seeds, cuttings, roots, and cions, weighing not over *thirty-two* ounces may be franked by the Department of Agriculture. Heretofore the limit was fixed at twelve ounces.

Seeds of Ailanthus and Sweet Gum.—Irwin Folsom, Rockland Co., N. H. The seeds are usually kept by Thorburn & Co., and probably by other large seed dealers.

Insects Received.—I. P. Allen, Whiteside Co., Ill., sends us the beetle of the borer, which infests the Locust. This is the *Clytus pictus* of the Entomologists. Mr. A. says that the borers are entirely ruining the Locusts in his county, and is afraid that they will attack the fruit trees. We have never heard that this particular borer injured any tree except the Locust. The perfect insect or beetle feeds upon the Goldenrods and some other wild flowers, but the eggs, we believe, are deposited in the crevices of the bark of the Locust only. James Strang, Franklin Co., Ohio. The striped insects are *Chrysomela vittata*, and the black ones *Lytta pennsylvanica*. They are both blistering beetles, and have been used as substitutes for the Spanish Flies of the shops. They are very destructive to potatoes and many other plants. Catching by shaking them into a pan of water, or by sweeping the plants with a net of muslin and then killing them by heat, has been recommended. Mr. Goodyear, Butler Co., N. Y. The caterpillar was too much decayed to make out satisfactorily, but it is probably the yellow-necked apple tree worm—a

most voracious fellow. Your method of getting rid of them by cutting off the twigs and burning them is certainly effectual. Vocative, Philadelphia. The insect which appeared upon the Oats is probably the grain aphid which has been frequently noticed in our pages. The young of the Lady-bug is not injurious to vegetation, but is one of the farmer's friends, as it lives upon plant lice.

Splendid Flowers.—There have been several collections of flowers upon the exhibition tables at the *Agriculturist* office within a few weeks, which are so very fine that they deserve more notice than a mere acknowledgement in our list of articles exhibited. The fine display of gladioluses mentioned last month has been kept up. Mr. W. P. Wright, of Hoboken, contributed the finest Asters we have ever seen—some were as large as a medium sized Dahlia. Mr. W. Davidson, of Brooklyn, has paid great attention to the cultivation of the Verbena, and has shown a large number of the old kinds and a great many of his new seedlings, comprising some very fine and distinct sorts. W. & J. Cranston of Hoboken, and Mr. Pell of the N. Y. Orphan Asylum, have made fine displays of Dahlias, and P. Henderson of Jersey City, has shown a collection of new Petunias, many of which were remarkably distinct in their markings.

Training Grapes upon Fences.—"T. C." Kinks Co., N. Y. If the fence is a tight one, nail on blocks or short pieces of boards, or iron brackets for the wires, to keep the vines six to twelve inches from the fence. Air should circulate freely behind them. Besides, the leaves would "burn" if in close contact with the fence.

The Beurre Clairgeau Pear.—This variety bids fair to sustain a good reputation for quality, while its great beauty is much in its favor. One of the finest sights we have seen in a long time was a dwarf tree of this kind in full bearing in the grounds of E. Williams at Mont Clair, N. J.

Ground-Glass Shades.—A correspondent in Maine questions the correctness of the opinion that the amount of light transmitted through a ground-glass chimney or globe is as great as that transmitted by plain glass, and cites a record of experiments in the *American Journal of Science and Arts* for November, 1860, on the loss of light by glass shades, from which it appears that, while common window and plate glass intercepted from 4 to 13 per cent. of the rays, ground glass intercepted about 65 per cent., or in other words, reduced the illuminating power nearly two-thirds.

"The Portrait Monthly."—T. B. Leggett & Co., Publishers of the N. Y. Illustrated News, have commenced issuing under the above name, a monthly sheet of 16 pages, of the size of the pages of the *Agriculturist*, giving engravings of the noted men of the day, mainly army officers, accompanied with short sketches of the life and acts of each man. The work is well printed on heavy paper, and is probably the best thing of the kind issued so cheaply (\$1 a year). Few of the hastily executed newspaper wood-engraved portraits, can be called very accurate, or satisfactory likenesses, yet they give some idea of the general features and expression of countenance, and hence are better than nothing. Good Photographs, or steel engravings are of course preferable, when they can be obtained.

"Veronica quinquefolia" and the Rural New-Yorker.—In the September *Agriculturist* we took occasion to publish an exposition of what we supposed came legitimately under the head of humbugs, that is, the puffing of the medicinal qualities of a very common herb, by communications in such papers as would print such matter, and its sale by the writer of the articles, at a very exorbitant price. Our much respected contemporary, the *Rural*, quotes our article, and then undertakes to prove us in error as to our botany. It is not our intention to make any statement that cannot be substantiated, and in the case in point we had beforehand abundant evidence of the truth of our assertions; evidence which can be produced should it ever be necessary. Our statement was, that the plant in question, though called *Veronica quinquefolia*, was the well known *Veronica Virginica*, also called *Leptandra Virginica*. We might have added that the name *Veronica quinquefolia* was one unknown to science. The *Rural* says that it has received a specimen of the plant from W. R. Prince, and goes on to show, from its botanical characters, that it is not *Veronica Virginica*, and indeed not a *Veronica* at all. As we do not know what plant has been sent to our friend by interested parties, we cannot say whether he is right or wrong in his conclusions, though we cannot help thinking that the number of characters he has made out, to show what the plant was not, ought to have enabled him to tell us what it was.

Our point was, that this "wonderful remedy," sold at a high price under the name of *Veronica quinquefolia*, was nothing but the old *Veronica* or *Leptandra Virginica*. That this is the case we can prove beyond doubt, and as a part of our evidence of this we quote from the catalogue of W. R. Prince & Co., published in 1844, where on page 102 we find the following:

"*LEPTANDRIA VIRGINICA*.—N. B. This plant is noted for purifying the blood, and for cures of salt rheum, leprosy and dropsy. For the quantity of the root and prescription \$5."

Aside from the incorrect spelling of the name, *Leptandra* can any one doubt that this is the same thing?

We do not think that our article contained any misstatement, except perhaps the price at which the root is sold. We learned from two sources that it was sold for \$3 per ounce and two ounces for \$5. We have now before us a circular, in which the price is given "3 ounces, \$3; 6 ounces, \$5; 9 ounces, \$7 50; and 12 ounces, \$10." Prices sufficiently high to warrant our calling them exorbitant, when the same article is readily obtainable at the drug and herb stores at about a dollar a pound. We have seen it growing abundantly, and generally along water courses. Of its medicinal qualities, the United States Dispensatory says: the "*Leptandra Virginica* or *Veronica Virginica*.... when recent, acts violently as a cathartic, and sometimes as an emetic.... It was formerly recognized in the U. S. Pharmacopœia, but was omitted in the edition of 1840."

The Ready Reckoner or Farmer's Manual, is the title of a work issued by Benj. Urner, N. Y., containing miscellaneous tables of measurement by farmers and others. With much useful matter it contains also information on many subjects of general interest, and is probably worth the price asked, \$1. The arrangement is very defective, the different subjects being thrown together heterogeneously.

A Californian Agricultural Fair.—We have the show-bills and programme of the Agricultural, Horticultural and Mechanics' Society of the Northern District of California, which held its fourth annual fair at Marysville during the week commencing the 7th of September. The premiums are ample and the rules liberal. As we received the announcement some days after the exhibition closed, we could not, of course, attend. We always receive these evidences of the agricultural prosperity of California with gratification, and we hope before we are many years older to witness the wonderful improvement it has made in the peaceful art.

Dwarf Broom Corn.—C. D. Ellis, Essex Co., N. J. This variety was first brought to our notice by Mr. E. B. Good, of York Co., Pa., from whom seed was obtained and distributed free to *Agriculturist* subscribers. It grows about four feet high, the brush being about two feet long. We have not recently heard anything concerning it, and do not know whether it was generally liked. The first reports from growers and manufacturers were favorable.

New-Jersey State Fair a Failure. We feel personally mortified at the doings of one of the members of the *Agriculturist* family. For New Jersey we have a special regard; it is near "head-quarters;" the *Agriculturist* is peculiarly the agricultural paper of the State, as none other is permitted to live there. There are plenty of good farms and good farmers in the State, and whatever they really undertake, they do up well, as a rule. Few other States have done more to furnish men for the national defence. Perhaps it was their special interest in the raising of troops just now, that led them to forget the State Fair held in the name of the New Jersey farmers this year. From our particular interest in this State, we were present at the so-called State Fair, while we only sent representatives to other States. A visit of three hours was enough. If there were a county in New Jersey (happily there is not) which could not get up a better agricultural show than the State affair this year, we should advise that county not to try. On the "State Fair Grounds" at Patterson the agricultural display contained only two sheep; about thirty cattle (including calves), such as they were; a baker's dozen of hogs and pigs; any number of fast horses; two plowmen at the plowing match; one firkin of butter and four boxes of cheese, or two of butter and three of cheese, we are not certain which; about a dozen melons; a few beets; less than a bushel of potatoes (where was Monmouth County?) and other vegetables to match in quantity. and any number of peddlers within the enclosure, including gift enterprises, chance operators, and the man who sang to the crowd, ladies included, songs that were little adapted to ears polite, if other songs were like one got off, as we were necessarily passing, about the peculiar effects of lager beer upon the two sexes.—The show as a whole (except the horse races, which we did not stop to see) was such a failure that we have no patience to speak of the few good

features we found in the fruit, household and implement departments. We regret to speak thus of the show of a State we have reason to especially regard, and do it "more in sorrow than in anger." Our only aim is to awaken the good farmers of New-Jersey to a sense of the disgrace put upon them, or perhaps put upon themselves, and to incite them to right action in the future. Monmouth County with its potatoes, and Bergen with its vegetables, can take the job and get up a big and useful display; but let the farmers of the whole State come together next year—at some central, accessible point—and show what New-Jersey can do when she tries. No State could beat her in a genuine exhibition of soil products.

Interesting to Flax and Hemp Growers and Manufacturers.—Congress having appropriated \$20,000 to be expended in investigations to test the practicability of preparing flax and hemp as a substitute for cotton, the Commissioner of Agriculture has placed the matter in the hands of three Commissioners, who call the attention of manufacturers to the subject. Samples of fibres and fabrics, with precise descriptions of processes, and statistics of cost, are to be sent to the Department of Agriculture at Washington, on or before November 20th. Parcels and letters should be endorsed, "For Commissioners of Flax Culture."

White Flax Seed.—Henry Gaylord, New Haven Co., Conn., sends us a sample of white flax seed, and asks if there is any difference between the fibre from this and that of the common seed. We have never seen the white seed before, except an occasional grain mixed with the brown and have no knowledge that the fibre is different from that of the ordinary kind.—We shall be glad to hear from any reader who can inform us.

What Success in Cotton Growing?—From many letters received last Spring we judged that a comparatively large area of cotton would be planted in some of the Northern States this year. Will those who have been engaged in the experiment please report to the *Agriculturist* their success or failure, and give such practical hints as their experience has suggested.

Large Yield of Potatoes.—Mrs. Elsie C. Wheeler, Essex Co., N. J., reports to the *American Agriculturist*, having planted a plot of ground, 61 feet by 89 feet, with Buckley's seedling potato, and realized a return of 39 bushels—over 312 bushels per acre.

Native Tobacco.—Geo. H. Brown, Henley, Cal., sends seeds and specimens of a species of tobacco which grows wild in all parts of California. We suppose, from the limited specimen, that it is *Nicotiana rustica*. We have not known of any attempts to cultivate it, and can give no idea of its value.

Tobacco for Ants.—W. B. Waldo, of Dutchess Co., N. Y., informs us that, after trying various expedients for ridding his walks of ants, at length succeeded in clearing them out by the use of a strong decoction of tobacco.

Pear and Peach Trees in Michigan.—J. N. Lansing, Mich. In your locality we should prefer to "heel in" the trees, i. e. make a deep trench for the roots and cover them with a good amount of earth, in a sheltered situation. Plum and Cherry trees we should prune in June or July. Currant bushes may be pruned any time in Autumn.

Night-blooming Cereus.—We have a fine specimen of this beautiful flower from Mr. George Stillwagon, of Flushing, L. I. Thanks to the attention of Mr. S., we had the pleasure of seeing it also.

Plants for a Name.—Mrs. N. Gougan, Wild Co., Ill., sends *Anagallis arvensis*, the Pimpernel, which she says is a cure for hydrophobia. We never before heard of its having any medicinal qualities.... "Spivins," Piqua, Ohio. The specimen came in rather bad order, but it seems to be *Quamoclit coccinea*, own brother to the Cypress Vine, and probably not a cross as you suppose.... S. A. Decker, (no place) sends the Bitter Sweet, described on another page.... Mr. Seelbach, Baltimore. The plant is probably *Cleome pungens*, but the specimen is too small for accurate determination.... H. H. Ackerman, Bucks Co., Pa. The seeds look like those of the Hollyhock, but as there are other nearly related plants, we can not be sure from the seeds only.... G. W. Goodwin, Conn., *Lythrum Salicaria*, the Spiked Loosestrife. It grows wild in some parts of your State, and is often cultivated.... Mrs. Julia H. Mack, Richland Co., Wis. The leaf sent is that of the Canarybird Flower (*Tropaeolum peregrinum*), a climbing species of the Nasturtium of the gardens. It is a charming climber, and an annual.

Probably the flower buds of your lilacs are winter killed.... E. W. Daniell, Meigs Co., Ohio. The grass is *Uniola latifolia*, the Broad-leaved Spike-grass. It is one of the most beautiful of our native grasses and worth cultivating for ornamental purposes.... Mariette M. Herring, Winnebago Co., Ill. Your plant is *Mertensia Virginica*, (formerly called *Pulmonaria*) the Virginian Cowslip or Lungwort. It is one of the most beautiful of our native plants, and better deserves cultivation than many imported ones. The plant is a perennial, and if it does not perfect seed, may be propagated by division of the root.... T. E. Goodrich, Ford Co., Ill., sends *Tradescantia Virginica*, noticed in the August basket. There are several varieties, all easily cultivated and very pretty. In botanical names when there are more than three syllables the accent is on the last but two, and thus: *Tradescan-ti-a Vir-gin-i-ca*. The name *officinalis*, which is often used as a specific name, comes from the Latin *officina*, a shop, and is applied to many plants which were or are sold as drugs in the shops.

Spontaneous Generation.—P. Garabrant, Morris Co., N. J., proposes to leave to the *Agriculturist* the settlement of the question "Will ground germinate grain or weeds if there are no seeds in it?"—If Mr. G. has read the back volumes of the *Agriculturist* he will have seen that we have taken very strong ground against spontaneous generation. We have no proof that plants are multiplied in any other than the way provided by nature. With all the knowledge we have at present, we should answer his question with an emphatic NO.

Mixing of Strawberries.—L. C. Church, Plymouth Co., Mass. It is likely that strawberries with perfect flowers will mix more or less, if planted together, but as this will not materially affect the fruit, it is of no practical consequence, unless you wish to preserve the seeds or plants of any particular kind in a pure state.

A Good Tomato.—The Fejee is a good tomato. It is of medium to large size, nearly smooth, of a dark red, or salmon color, with a solid, meaty flesh, and is of fine flavor. If tomatoes were sold by weight—which really gives their value—the overgrown, deep scalloped sorts which have to be broken into pieces before they can be peeled, would be discarded. Any smooth, solid tomato is preferable to the irregular ones, but commend us to the Fejee, *alias* Lester's Perfected.

"Big Things."—J. D. Ellis, Columbia Co., N. Y., writes to the *American Agriculturist*, condemning the mania for producing "big things." He asks, "Why is a pumpkin weighing 200 lbs. better than five weighing 40 lbs. each; or a strawberry that must be carved like a muskmelon, more desirable than a larger number averaging one to a mouthful?" In some things, undoubtedly there is little gained by enlarging specimens to unusual size; but in many fruits and vegetables large growth gives superior quality. Thus the apple, peach, cherry, etc., are improved by increase of size. But even where this is not the case, producing extraordinary specimens is merely a gratification of curiosity, an innocent though perhaps unprofitable amusement.

Great American Exhibition of Pumpkins, Squashes, and Ornamental Gourds.

The Second Annual Exhibition of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS, at the office of the *American Agriculturist*, 41 Park Row, New York City, opens on Wednesday, Nov. 4th, 1863, and the following Prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

A—For the Heaviest Pumpkin or Squash.....	\$10.00
B—For the 2nd Heaviest Pumpkin or Squash....	5.00
C—For the 3d Heaviest Pumpkin or Squash....	3.00
D—For the Best Pumpkin or Squash for cooking.	5.00
E—For 2nd Best Pumpkin or Squash for cooking.	3.00
F—For the largest yield on a single Vine.....	10.00
G—For the 2nd largest yield on a single Vine....	5.00
H—For the largest and finest collection of Fancy or Ornamental Gourds.....	7.00
I—For the 2nd largest and finest collection of Fancy or Ornamental Gourds.....	4.00

*All to be grown by one person and to be accompanied by positive evidence from the grower, and one disinterested person who assists in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at auction, or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 15th, and deliver specimens for competition on or before Nov. 2d. Specimens to be delivered free of charge.

Note 3.—The same specimen can compete for only one of the premiums offered above. See note, page 292.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed on our tables for exhibition since our last report:

FRUITS.—Apples: Red Astrachan, from A. J. Hall, Wallingford, Conn.... Specimens for name, and St. Lawrence; T. Briggs, Schaghticoke, N. Y.... Benoni Apples, fine; James Weed, Muscatine, Iowa.... Hyslop Crab Apple, (described under "Basket:"); H. A. Conger, Whitewater, Wis.... Specimens kept from last year; Wm. Tefft, Fordham, Mass.... Specimens for name; Wm. Howe, Mt. Vernon, N. Y.... Cranberry Pippins grown in 1862, very fine; Robert Benner, Astoria, N. Y.... Pears: Bartlett and Doyenne Boussock; Wm. Doty, Union Hill, N. J.... Specimens for name; Wm. Van Brunt, L. I.... Fine clusters of Seckels; Peter Voorhees, Nyack, N. Y.... Peaches: Specimen for name; J. W. Hughes, Staten Island, N. Y.... Fine basket Crawford's Early; C. W. Idell, West Washington Market, New-York City.... Seedling; Wm. L. Plume, Brooklyn, N. Y.... Grapes: Hartford Prolific; Prof. Hopkins, Metuchin, N. J.... Hartford Prolific; Wm. H. Mitchell, Harlem, N. Y.... Northern Muscadine and Hartford Prolific; G. R. Garretson, Flushing, L. I.... Early Canada or August Grape; Mr. Ripley, South Windsor, Conn.... Hartford Prolific; Wm. Tefft, Fordham, Mass.... August Pioneer; John Friske, Holliston, Mass.... Berries: Cut-leaved Blackberry; S. A. Halsey, Astoria, N. Y.... Lawton Blackberry; Jno. B. Peck, Yonkers, N. Y.... Twice bearing Raspberry, Belle de Fontenay, Pink Blackberries, and late Strawberries; Wm. F. Heins, Morrisania, N. Y.... Miscellaneous Fruits: Ripe Figs, large and fine; M. J. Taylor, Jr., Southport, Conn.... White Japan Melon; Mr. Godfrey, Westport, Conn.... Skillman's Netted Musk Melons, splendid specimens; Richard Bennett, Fort Hamilton, N. Y.... Plum for name; L. Pfenniger, Brooklyn, N. Y.... Cape Cod Cranberry Plant, in fruit; Wm. H. Starr, New-London, Ct.... Nectarine; B. N. Leonard, Brooklyn, N. Y.

FLOWERS.—Cut Flowers and Asters in pots; O. Judd, Flushing, N. Y.... Dahlias, Carnations, Roses, etc., C. S. Pell, New-York Orphan Asylum.... Canna Indica, very fine; Wm. F. Heins, Morrisania, N. Y.... Fine colored Seedling Petunias; Peter Henderson, Jersey City, N. J.... Balsams; Mr. Petrick, Union Hill, N. J.... Double Sunflower, *Imperiale*, perfect specimen, Lewis A. Burt, Tremont, N. Y.... Magnificent collection of Gladioluses; Andrew Bridgman, 873 Broadway, New-York City.... Dahlias, Seedling Phloxes, Petunias, Heliotropes and Double Balsams, very superior; W. & J. Cranston, Hoboken, N. J.... *Bilbergia fulgens* in bloom; Isaac Buchanan, West 17th-st., New-York City; Night-blooming *Cereus triangularis*; A. P. Cummings, New-York City.... Cut Flowers; Mrs. John Harper, East 82d-st., New-York City.... Splendid collection of Seedling Verbenas; Wm. Davison, Brooklyn, N. Y.... *Caladium nymphaeifolium*; Wm. Heins, Morrisania, N. Y.... Magnificent collection of Asters and Zinnias; W. P. Wright, Weehawken, N. J.... Balsams, Prince's Feather, Coxcomb, and Fancy Gourds; Wm. B. Westcott, 303 Madison-st., N. Y.... Balsams; Mrs. Wm. Hamon, N. Y.

VEGETABLES.—Curious growth of Sweet Corn; Wm. Bergen, East New-York.... Cucumber grown in Bottle; E. W. Probasco, Clinton, N. J.... Tree Tomato, extra; G. M. Usher, Port Richmond, N. Y.... Cucumber and Melon hybridized; H. W. Olcott, Mt. Clair, N. J.... Fejee Tomato; Dr. A. Barber, Brooklyn, N. Y.... White Cucumber, very fine; W. G. McLaughlin, Harlem, N. Y.... Cuban or Grape Tomatoes; W. M. Doty, Union Hill, N. J.... Long Blood Beet, Red Turnip, Yellow Tomatoes, Curious growth of Carrot and Tomato, superior Corn, and Lima Beans; J. W. Perkins, St. Joseph's Hospital, N. Y.... Purple Egg Plant, improved variety, White Egg Plant, Okra, Beefsteak, Yellow Plum, Yellow Cherry, Red Plum, Fig, Apple, and Cuban Tomatoes, and Winter Cherries; Wm. F. Heins, Morrisania, N. Y.... Large Purple Egg Plant, weighing 4½ lbs; John G. Freeman, Ravenswood, N. Y.... Sugar Beets; John B. Vroom, Blooming Grove, N. Y.... Fancy Gourds; Daniel Rankin, Mt. Vernon, N. Y.... Peach-Blow Potatoes, good, first crop from Scrub-Oak land; M. Foley, Central Islip, N. Y.... Two Purple Egg Plants, very large, weight 5½ and 7½ lbs; Mrs. A. A. McElwec, Walker Valley, N. Y.... Cucumber, 3½ lbs., and Long-necked Squash, 20 lbs.; W. C. Aubert, New-Durham, N. J.... Fejee Tomatoes; W. W. Davis, 130 Grand-st., Jersey City, N. J.... Tree Tomato, curious specimen; G. M. Usher, Port Richmond, N. Y.... Purple Egg Plant, largest, weight 8 lbs. 10 oz.; Robert McGarrety, gardener to Frederick Wiggins, Rye, N. Y.

MISCELLANEOUS ARTICLES.—Specimen of Raw Silk, O. U. de la Harpe, Great Salt Lake City, Utah.... Red Currant Juice preserved in bottle; Wm. M. Doty, Union Hill, N. J.... Mediterranean Wheat; A. Milne, Stamford, Conn.... Mammoth Millet; Mrs. A. A. McElwec, Walker Valley, N. Y.... Fruit of Skunk Cabbage, (*Symplocarpus foetidus*); J. M. Knowlton, Tarrytown, N. Y.

Fig. 1.—ELEVATION OF PIGGERY.

Care of Swine—Plan of a Piggery.

Because swine are blessed with keen appetites, strong digestion, and hardy constitutions capable of resisting a great amount of neglect and ill-usage, they have been, and in too many instances yet are, the worst used animals kept for the profit of man. And as if to add to the abuse, their endeavors to make the best of ill treatment, has been charged to the account of their natural uncleanness, and the idea that wholesome meat can not be made by feeding animals with garbage, has caused pork to become the horror of dietetic reformers, who pronounce it unfit for human food. It were as wise to condemn the use of milk, and to pronounce cows unfit for civilized communities, because some individuals persist in confining them in filthy stables, and dosing them with distillery slops. In his native state, the hog is as dainty in his taste as other animals, and his lair is found in a dry situation, well cushioned with clean leaves, unsoiled by any neglect of his own. Civilization has affiliated him with the degraded members of the human species, and brought his name to reproach by associating it with the vile among men. Within a few years past, however, a change for the better has been apparent, and many readers of the *Agriculturist* are inquiring for good plans for piggeries, for the best methods of rearing and fattening swine, and other kindred matters pertaining to their welfare and ultimately to the profit of their owners. It would be within the mark to say that in most instances, twenty per cent of saving can be effected in food, and in additions to the manure heap, by a well regulated building for the accommodation of swine. We therefore take pleasure in laying before our readers the accompanying illustrations engraved from plans forwarded by Mr. Roseburgh, of Amboy, Ill. They were designed and constructed for use on his

building is 22 by 50 feet, and the wing 12 by 16 feet. It is supplied with light and air by windows in front, ventilators on the roof, and by hanging doors or shutters in the upper part of the siding at the rear of each stall or apartment—these last are not shown in the engraving.

Fig. 3, shows the ground plan. The main building has a hall, *H*, 6 feet wide, running the entire length. This is for convenience of feeding, and for hanging dressed hogs at the time of slaughtering. The remainder of the space is divided by partitions into apartments, *A*, *B*, for the feeding and sleeping accommodation of the

Fig. 3.—GROUND PLAN OF PIGGERY.

porkers; these are each 8x16 feet. The rear division of each apartment, *B*, *B*, is intended for the manure yard. Each apartment has a door, *D*, *D*, to facilitate the removal of manure, and also to allow ingress to the swine when introduced to the pen. The floors of each two adjoining divisions are inclined toward each other, so that the liquid excrements and other filth may flow to the side where the opening to the back apartment is situated. Two troughs, *S*, *T*, are placed in each feeding room. That in the front, *S*, is for food, and *T*, for clear water, a full supply of which is always allowed. This is an important item, generally overlooked; much of the food of swine induces thirst, and the free use of water is favorable to the deposition of fat.

An excellent arrangement (shown in Fig. 2,) is adopted to facilitate the cleaning of the troughs, and the transferring of the hogs to the main hall at slaughtering. The front partition of each apartment, *F*, (fig. 2,) is made separate,

and contrived so as to be swung back, and fastened over the inside of the trough, *T*, at feeding time, or when cleaning the trough. It may also be lifted as high as the top of the side partition, *H*, when it is desired to take the hogs to the dressing table. Triangular pieces, *E*, *E*, are spiked to each front partition, and swing with it, forming stalls to prevent their crowding while feeding. These are supported, when the apartment is closed, by notches in the inner edge of the trough, made to receive them.

The wing, *W*, is 12 by 16 feet. This answers for a slaughtering room. In one corner, adjoining the main hall, is a well and pump, *P*, from which, by means of a hose, water is conveyed to the troughs. At the opposite corner, *K*, is a large iron kettle, set in an arch, for cooking food, and for scalding the slaughtered swine. We would suggest that in many localities it would be a desirable addition to have this wing built two stories high, the upper part to be used for storing grain for the hogs, and also that a cellar be made underneath for receiving roots.

The Care of Horses.

Some persons, in their anxiety to subdue their horses, take every opportunity to worry and beat them, "to let the beasts know who is master," they say. They whip, scold, and beat them on principle. Now, who does not know that such treatment addressed to a child, with the idea of subduing him, would inevitably sour his temper, and render him disobedient and obstinate? As certainly will this be the case in the discipline of a domestic animal. Instead of this, it should be our aim to let the horse know and feel that we are friendly to him and desire his well-being. This may show itself by avoiding whatever will tend to annoy and provoke him, by kindness in the tone of voice, in the way of handling him, by occasionally fondling and stroking him, and by various unmentionable things which will at once occur to those

familiar with this noble animal. He will understand their meaning, and they will affect his character. A horse so treated, will be a pleasant beast to handle, he will keep and fatten better, will be in better health, and will do more work than one managed differently. This should be done from the animal's earliest years, but even if neglected while young, the horse may thus be taught to love his owner.

Regularity and system.—This will show itself in determining the time and amount of feeding and of working. Nearly all the diseases to which the horse is subject, come from irregularity in these respects. If he is under-fed and over-worked, the tone of his system will become relaxed, and disease be likely to set in. So if he is over-fed, and has deficient or irregular exercise, he will contract another set of diseases. The man who is regular and systematic in his own habits of living, is most likely to enjoy health and long life, while he who indulges in

Fig. 2.—FRONT PARTITION.

own premises, and have therefore the merit of being the production of a practical man.

Fig. 1, represents the elevation. The main

excesses of any kind is sure to suffer from frequent and violent attacks of illness, and end his days prematurely. It is hardly less so with man's favorite animal, the horse.

Change of diet, cleanliness, and good shelter should not be overlooked. For the horse running at large, as in the wild state, the diet which nature gives him is all-sufficient, but for one confined, stabled, and worked, much attention should be given to his food. Hay and oats are doubtless the best food, all things considered, but even these should have an occasional variation. Carrots, potatoes, bran, fresh cut grass, should be given him in their place and time. During Summer it seems only simple justice that, when practicable, the horse should be treated for a time to that food which is most natural to him—fresh grass. If every stabled, hard working horse could have a summer vacation of several weeks in a pasture, it would soften his dry and cracked hoofs, correct his digestion, improve his wind, his skin, and indeed renovate his entire system. But where this indulgence can not be enjoyed, a horse should have frequent messes of loosening food, such as roots, bran mashes with cut straw, fresh grass, etc.

As to cleanliness, both good looks and health demand this. A horse well curried will make a peck of oats go much further than one ungroomed. Good shelter saves many a horse from taking cold when coming in from work, and adds much to his health and daily comfort.

Diseases in Animals—A Useful Society.

Announcement is made in English Journals of the formation of a "Society for the Prevention of Disease among Domestic Animals." The prospectus declares that in Great Britain, live stock to the amount of \$30,000,000 is annually destroyed, principally by contagious diseases. It is proposed by the Society to aid in reducing this enormous loss, by collecting information and statistics concerning the diseases of animals; by affording advice and assistance to stock-owners, wherever general outbreaks of disease occur; by ascertaining periodically the health of stock in the countries from which foreign animals are derived; by stimulating inquiry as to the most advantageous means of disposing of diseased animals or their produce, so as to secure the largest amount of salvage for stock owners, and by adopting all possible means to check such a traffic in diseased animals as tends to the spread of plagues, or to the sale of diseased meat to the public.

This movement is not without interest to stock breeders on this side the Atlantic. The importation of cattle and sheep to the United States is yearly increasing, and already we have had in the pleuro-pneumonia excitement, an experience of the disastrous results which may come without some proper precautionary measures. It would undoubtedly be a proper subject for legislation to devise means whereby the importation of diseased animals could be prevented. Quarantine laws are very stringent as regards persons coming from unhealthy ports, and it need not be stated that the sale of diseased animals often proves of fearful detriment to the public health. But, as all are aware, years of agitation and discussion of a subject are usually required before legislative action can be had, and meantime, the evil may be upon us. We know of no way in which the matter can better be brought before the public, and if needed, the enactment of proper laws be finally secured, than by the formation of a

society similar to the one referred to above. This subject may well claim the attention of State Agricultural Societies, and to their especial notice we commend it.

Glanders in the Horse.

The most marked symptom of this fatal malady in horses, is a discharge from one or both nostrils. As, however, the same appearance may follow other less severe disorders, no horse should be condemned as glandered, unless other well marked indications of this disease are observed. Mayhew in his "Illustrated Horse Doctor," gives in substance the following directions for making an examination of a suspected case. The animal's head should be turned toward the strongest light attainable. The examiner should then place himself by the side of the horse's head, not in front, but in a situation where, if the animal snort, the person is in no danger of having the ejected matter thrown upon him. Such an occurrence might be followed by the most serious consequences, as the discharge from glanders is very poisonous, and if absorbed into the system would cause death. The examiner should raise the wing of the nostril and inspect particularly the membrane situated more internally than the skin, seen at the commencement of the nostrils. This membrane is easily distinguished by its fleshy and moistened aspect, as well as by its situation, the termination of the skin being marked by a well defined margin. If, on this membrane, any irregular or ragged patches are conspicuous, if these patches are darker toward their edges than in their centers, and if they nevertheless seem shallow, pallid, moist, and sore, the animal may be rejected as glandered. Should any part of the membrane after having been wiped with a bit of tow, seem rough, or have evidently beneath its surface, certain round or oval shaped bodies, the horse is assuredly glandered. The membrane may present a worn eaten appearance, or be simply of a discolored, and heavy hue. In the first case the animal ought to be condemned; in the second, it is open to strong suspicion. The other general symptoms of glanders are: first, loss of appetite, quickened pulse, and a staring coat. Soon after, a slight discharge issues from the nostril, and usually one of the lymphatic glands grows fast to the jaw, becomes hard and insensitive, and from being wholly imperceptible in the healthy animal, enlarges to about half the size of a chestnut. Ultimately the discharge thickens, encrusting the hairs over which it flows, and adhering to the edges of the nostril. This is finally followed by ulceration of the internal parts of the nose, until death relieves the animal.

No successful treatment has yet been found for glanders, and hence the greater necessity for prevention. It may result primarily from the impure air of ill ventilated and foul stables, from neglected catarrh, or from long continued exhausting labor, with stimulating food. It is also highly contagious, so that the infection may be taken from a stable where a glandered horse has been kept. An animal in high condition contracting this disease by infection, will usually have it in the most acute form, and die within a short period. If it has been engendered by natural causes, it may remain chronic and in an undeveloped stage for years. Horses in such a case are most dangerous, as they are capable of imparting the disease to others, while it may not be suspected in themselves. When once it is clearly determined that a horse is thus

afflicted, the sooner he is dismissed from the world, the better for him and the community.

The Bar Horse-Shoe.

Though it is not advisable to adopt this shoe often, or long at a time, there are occasions when it is very useful. By continuing such a shoe around the heels, the pressure is taken off from one part and is equally diffused over the whole. Obviously, such a contrivance is beneficial when the hoof is cracked, when corns appear, and in cases of thrush. After it has been worn three or four weeks, or as soon as the disease abates, it should be dispensed with. If not taken off, the frog of the foot will suffer under the continued pressure of the bar. Whenever this shoe is used, care should be taken in driving to avoid slipping. Neither heavy draft nor great speed should then be required of the horse.

Scratches in Horses.

C. G. Siewers, Campbell Co., O., gives his experience as follows: "The best remedy I have every tried is to walk the horse up and down in running water two or three times a day, for a few days; this always cures my horse. The cause I ascribe to a filthy stable, as my horse never gets the scratches, unless I employ a certain lazy farm hand in the neighborhood of a make-shift; he and the scratches come together."

How to Send Grain to Market.

To the Editor of the American Agriculturist:

It is unaccountable to me that so many farmers have not yet learned how to send hay and grain to market, so as to make them pay the most profit. I see boat loads and car loads of such produce passing through my neighborhood on its way to your city, hundreds of miles distant. It brings prices that would make a Western farmer's pocket jingle merrily, only that a large part of the money stops in the hands of the transporters, to pay freight. Now, railroads and canal boats are excellent institutions, but I have never yet found so good a way to send corn to market, as on the four legs of a well fattened animal. A bullock, or a hog will pack away a few bushels of corn more snugly than any freight master could do, and it brings better prices after they have worked it over into beef and pork, than in the raw state. With the exception of wheat, and perhaps rye, I would not sell a peck of grain from my farm, except for seed. Along in the Summer, when pasture is scarce, and plenty of cattle are to be picked up, I secure enough to consume all the corn I can spare, over what will be needed to fatten my hogs, (these I raise at home,) and just before cool weather commences, I set the beef factories to work. The chips give me profit in the shape of manure, enough to make the operation pay, even if I could only get the same price for the grain as before feeding it out; but there is a gain here, too. When I read about Illinois farmers and others using corn for fuel because it is cheaper than coal, I think they need instruction on this point. If they have not capital enough to buy stock to eat up their grain, let them borrow the cattle, and agree to return so many pounds of fattened beef, for each animal, in the same way that sheep are taken on shares; it would be mutually beneficial to themselves, and to those who have more animals than they can keep profitably. I

know that many men living on new lands will laugh at the idea of using manure, but the laugh will be on the other side not many years hence, when their lands begin to show signs of weakness, as those of western New-York have done. It is very easy to keep a soil fertile, but a slow and costly operation to restore a worn out one. But whether the manure be used or not, I believe it will be found to pay to feed out grain before sending it to market. JONATHAN.

Sale of South-Down Sheep at Thorndale

The large amount of space devoted to a full report of the sale of South-Down sheep from the flock of Mr. Samuel Thorne, is justified by the fact that it is of general, we may say national importance. The beneficial influence which the dispersing of such improved stock through the country will have on our flocks, can hardly be estimated. As is well known, the animals disposed of by Mr. Thorne, were descendants or direct importations from the best flocks in the world, and it may be questioned whether a collection of sheep can be found even in England, superior to that from which these were sold. In answer to inquiries made of Mr. Thorne, we learn that the 81 ewes disposed of as reported below, yielded at the last shearing 419 lbs. of clean wool, an average of 5 lbs. 2½ ozs. per head. The rams were shorn unwashed, and gave from 8 to 12 pounds per head. Another fact of much interest may be stated for the benefit of many readers of the *Agriculturist*, who have made inquiries upon the subject. A cross of the South-Down ram upon the Merino ewe, produces the finest sort of lambs for marketing. This has been practised at Thorndale for years, and, Mr. T. informs us, has proved one of the most profitable parts of sheep husbandry.

The recent sale, held Sept. 2d, was very well attended, the day being propitious, and the bidding was spirited, although prices were hardly what might have been anticipated in view of the demand for sheep, and the reputation of the flock. However, as will be seen below, enough was realized to prove that the raising of improved sheep is a business that will pay. Want of space compels us to omit further introduction.

EWES. YEARLINGS.

1. Ewe by Archbishop, dam by No. 6, grand dam an imported Ewe, from the flock of Henry Lugar, Esq.; To P. W. Jones, Amherst, N. H. \$25 00
2. Do. by do., dam by imported Prize Ram, 112, g. dam an imported Ewe as above; J. C. Tatum, Woodbury, N. J. \$22 00

Average. \$25 53

RAMS.

1. Imported Prize Ram Archbishop; G. H. Brown, Washington Hollow, N. Y. \$500 00
2. He was selected and purchased from the flock of the late Jonas Webb, Esq., in 1850, at a cost of 250 guineas, (\$1250). He won the 1st Prize in the Yearling Class that season at the Royal Show, and, as will be seen by reference to the Catalogue of Mr. Webb's last Southdown Sale, was used more largely by him than any other Sheep.
3. Three yrs. old Ram by Young Salisbury, dam an imported Prize Ewe; John Bard, Barrytown, N. Y. \$50 00
4. A two yrs. old by No. 5, dam by No. 6, g. dam an imported Prize Ewe; G. Armstrong, Orange Co., N. Y. \$25 00
5. Do. bred by the late Jonas Webb, Esq., got by 88, dam by Reserve; E. Thorne, Po'keepsie, N. Y. \$125 00
6. Do., same as No. 4; Josiah Kirk, Sag Harbor, L. I. \$40 00
7. Yearling, by No. 14, dam by Young Salisbury, g. dam by 112, gr. g. dam imp. Webb Ewe; J. C. Tatum, Woodbury, N. J. \$30 00
8. Do. by Archbishop, dam an imp. Webb Ewe by Reserve; Thos. George, Newburgh, N. Y. \$52 00
9. Do. by do., dam an imp. Webb Ewe, by Young Norwich; P. W. Jones, Amherst, N. H. \$17 00
10. Do. by do., dam an imp. Webb Ewe, by Reserve; Sanford Howard, Boston, Mass. \$131 00
11. Do. by do., dam by Young Salisbury, g. dam by 112, gr. g. dam imp. Lugar Ewe; J. Robinson, Clinton Corners, N. Y. \$38 00
12. Do. by do., dam by No. 6, g. dam an imp. Prize Ewe; A. W. Storie, Dutchess Co., N. Y. \$30 00
13. Do. by do., dam by No. 6, g. dam by 112, gr. g. dam an imp. Richmond Ewe; J. O. Sheldon, Geneva, N. Y. \$55 00
14. Do. by do., dam by Young Salisbury, g. dam by 112, gr. g. dam an imp. Lugar Ewe; E. M. Bottsford, Newtown, Conn. \$26 00
15. Do. by do., dam by 112, g. dam an imported Prize Ewe; Sanford Howard, Boston, Mass. \$57 00
16. Do. by do., dam by 112, g. dam an imp. Prize Ewe; E. Thorne, Po'keepsie, N. Y. \$70 00
17. Do. by do., dam by 19, g. dam by 112, gr. g. dam imp. Richmond Ewe; P. W. Jones, Amherst, N. H. \$11 00
18. Do. by do., dam by No. 6, g. dam an imp. Prize Ewe; Wm. Hurst, Albany, N. Y. \$50 00
19. Do. by do., dam an imp. Webb Ewe by Reserve; Sanford Howard, Boston, Mass. \$35 00
20. 6 yrs. old, by 112, dam an imp. Prize Ewe; F. P. Kincaid, Spring Station, Ky. \$50 00

Average. \$73 26

Two of the animals advertised, Lots No. 63 and 65, died before the sale, leaving 109 the number actually sold. The average price obtained for the whole was \$44.92.

THE RAMS REFERRED TO IN THE FOREGOING PEDIGRES, ARE AS FOLLOWS:

112, (Gaiety,) was imported from the flock of the late Jonas Webb, in 1835. Winner of 2d Prize at the Royal Show at Lewes, was purchased at Mr. Webb's Annual Letting for 130 guineas (\$650).

No. 6, sire 112, dam an imported Webb Ewe. He was winner of First Prize at the U. S. Show in 1850, and of First Prize in Aged Class at N. Y. State Fair in 1859.

No. 19, sire 112, dam an imported Prize Ewe.

Young Salisbury was bred by the late Jonas Webb, sire the First Prize Yearling Ram at Salisbury.

No. 14, bred by Wm. Rigden, Esq., Brighton, England. Winner of the First Prize at Chichester in 1860.

No. 5, sire 112, dam an imported Ewe from the flock of Henry Lugar, Esq.

No. 30, sire No. 6, dam by 112, g. dam an imp. Webb Ewe. Winner of First Prize in the Aged Class, at the N. Y. State Fair at Watertown, in 1860.

Spreading Straw, or Composting it.

We are often told of the fine effect produced by simply spreading straw on land in the Fall, and allowing it to lie and rot. It protects the roots of clover and grain in the Winter, and shields them from burning suns the following Summer. This practice is common at the West and South. On the large wheat fields of those sections, it would be quite laborious to haul grain home to the barn-yard for threshing, as we do at the North and East, and then after it had been fed out or mixed with manure, to cart the straw dung back again in the Spring.

The western plan doubtless has its advantages. Yet we question whether the waste of straw is not more than enough to pay for the extra labor required by the eastern practice. When left on the field, straw has little manurial value. It is dry, woody matter, and amounts to little more than a good mulch. If drawn to the cattle sheds and housed, it would serve in part as a coarse fodder, and as litter for all kinds of stock. It is of no slight importance to keep stock clean and warm in Winter. Then, by absorbing their liquid excrements and being mixed with the solid, it makes a large stock of valuable manure.

Fig. 1.—BITTER-SWEET (*Solanum Dulcamara*.)

Talks About Weeds....V.

POISONOUS PLANTS.

Several inquiries have recently been made at the office of the *Agriculturist* concerning the alleged poisonous qualities of two very common plants, the Bitter-Sweet, and the Nightshade. These are both species of the genus *Solanum*, to which the potato also belongs. The Bitter-Sweet is *Solanum Dulcamara*, a perennial half-shrubby vine, with leaves presenting a considerable variety in shape, but generally with two ear-like lobes at the base like those represented in the engraving. The flowers are borne in clusters, their purple star-shaped corollas and bright yellow stamens making them quite showy: these are followed by a berry about the size of a pea which is bright red when ripe. In Autumn, the brilliant fruit of the vine makes it very conspicuous and attractive. The plant is sometimes cultivated as an ornamental vine; it runs to the height of 8 or 10 feet, and is used like other climbers to cover walls and unsightly buildings. Bitter-Sweet is a native of Europe, but it is found growing wild in most of the settled portions of this country. It is found in waste places, along the borders of meadows, etc. A recent case, in which three children died suddenly, was attributed to poisoning by eating the fruit of the Bitter-Sweet. It is not known positively that the children partook of the fruit, but as there was a plenty of it to which they had access, it is supposed that it caused their death. Since this circumstance came to our knowledge, we have been at some pains to look up the records, and find that there is a great diversity of opinion as to the poison-

ous character of the berries. Some high European authorities state that they are positively deleterious, while others declare that they are harmless. We can only account for this diversity of opinion by supposing that difference of soil might vary the character of the plant. It is well known that the active properties of plants are greatly modified by differences of climate. We are disposed to regard the plant with suspicion. An infusion of its twigs is sometimes used medicinally, and narcotic effects have been produced by an overdose; although it does not follow that the berries possess the same properties as the twigs, yet in the present uncertain state of our information, we should advise discarding the plant altogether from cultivated grounds. The berries are so showy that they are likely to tempt children to eat them; though we can not say that they are poisonous, we are not able to say that they are harmless, and we would advise our readers not to tolerate the plant, as the risk is altogether too great.—Another species, *Solanum nigrum*, the Common Nightshade, is very common about dwell-

ings, and is often found as a weed in gardens. It is a coarse annual, 1 to 2 feet high, and very much branched. Figure 2 will give an idea of the shape of the leaf. The flower is white and the berries black. This plant is much more common than the Bitter-Sweet, but not being so showy either in its fruit or flowers, is much less

Fig. 2.—NIGHTSHADE (*Solanum nigrum*.)

likely to be noticed. The remarks upon the poisonous qualities of the Bitter-Sweet will apply also to this. It should be exterminated.

A "Shocking Horse."

This name does not, in the present instance, indicate a four-legged beast afflicted with heaves, spavin, etc., but a simple contrivance to facilitate the shocking or "shooking" of corn, as cut at the ground. Though long in use in some parts of the country, and heretofore described in the *Agriculturist*, it may be new to many of our readers. It consists of a light pole, *a*, 16 to 18 feet long, with two supporting legs 5 feet from

the end, and a cross pin, *b*, about 4 feet long, 2 feet from the end, at right angles with the pole. This pin should be about an inch in diameter, and the hole to receive it made large enough to allow it to be slipped in or out easily. This implement is to be placed with the pin where the shock is to stand, the stalks set up in the four corners, and when the shock is made, the pin and pole may be withdrawn and the apparatus moved to the place for the next shock. It will save considerable time in setting up the first stalks, which are usually placed about a standing hill, and will also obviate the necessity of afterward tearing open the shock to get at the uncut stalks, when the corn is to be husked.

Wheat on Clover Sod.

C. S. Mason, Wayne Co., N. Y., writes to the *Agriculturist*: "I have always had the best success in sowing wheat on sod ground. I mow clover one year only for hay, and after cutting, turn the sod under five or six inches deep, and harrow lengthwise once, and then diagonally once. The wheat is drilled in from the first to the tenth of September. Sod ground will stand drouth, or if the season be wet, the water has a chance to drain off. The wheat grows strong in Autumn, stands Winter better than if sown after barley, oats, or peas, and ripens early."

[We know by successful experience and by much observation, that turning under a heavy growth of clover, is an excellent preparation for a wheat crop. The clover gathers from the atmosphere a large amount of nitrogenous material, which is specially adapted to the wants of wheat, while the buried roots and stems help to keep heavy soils light and porous. Our practice at the West was to sow clover on the wheat in Spring, pasture it in Autumn, mow the next year, and then turn under a heavy second growth, and sow wheat directly upon it, without a second plowing. Or, after having pastured it in Autumn, the following Spring the stock were kept off, and the first growth was plowed in while in bloom. This was left fallow, the weeds were harrowed down occasionally, and in Autumn the field was thoroughly harrowed and cross-harrowed, and the wheat was sown. This latter plan was adopted when the wants of stock required the pasturage in Autumn, or when the soil needed recruiting by the heavy sward and first large growth of clover. This treatment gave an increased crop of wheat every second or third year on the same land, besides the hay and pasturage.

When needed, a top-dressing of plaster was sown on the wheat in Spring, with the special object of promoting a strong growth of clover. The effect of this application was very distinctly seen, when a land was left unplastered.—Ed.]

Miles' Improved Sap Boiler.

The apparatus represented in the above illustration was devised by Henry Miles, Addison Co., Vt., who sends a drawing and description for the *American Agriculturist*, with the remark that it is not yet patented, and perhaps never will be. It was intended for evaporating maple sap, but is equally applicable to boiling down sorghum juice. As it contains some novel features, which Mr. Miles considers valuable, we publish it for general examination. In the sketch, A, represents the arch, built in the ordinary manner, to accommodate the boiling pan, B, resting upon it. The pan is of sheet iron, 20 inches wide, and 6 inches deep. A rim of hemlock strips, $2\frac{1}{2}$ inches wide, fitting close within the edge of the pan, is added to prevent the sap or syrup from boiling over. The pan is furnished with a faucet, F, through which to draw off the syrup. A cover of boards, C, nearly steam tight, is placed over the pan, resting upon the rim. In this cover, $1\frac{1}{2}$ inch holes are bored to receive hollow posts or tubes, T, T, to convey the steam to a wooden conductor, D. These posts or tubes are each 9 inches long, and $2\frac{1}{2}$ inches in diameter. The dimensions of the conductor are not given, but the drawing indicates a wooden box with an interior, 12 inches wide, and 3 inches high. The conductor, D, conveys the steam to the steam box, S, (dimensions not given) in which rests the heater, H, a sheet iron pan, 20 inches square and 3 inches deep. An opening from the steam box, not shown in the engraving, allows the escape of the waste and condensed steam. A wooden tube, E, passes from the heater, H, to near the bottom of the boiling pan, B. The reservoir, R, for receiving the cold sap, is placed above the level of the heater, H, and is connected with it by a tube.

The object of this arrangement, as will be readily seen, is to use the steam escaping from the boiling liquid, to heat the raw sap before its introduction into the boiler. At first it would seem that any obstruction interposed to the freest escape of the steam, would require an increase of heat and consequently of fuel to expel it, and that this would more than counterbalance any advantage accruing from heating the sap with the steam. Mr. Miles asserts that his experience and that of his neighbors, has proved that there is an actual gain in fuel by covering the boiling pan, from the fact that the external cold air is excluded, which would abstract a

great amount of heat from the boiling surface. He says that the steam will take good care of itself, and find its way out without any difficulty, and that the heat imparted in its passage through the condensing box, will be sufficient to raise the cold sap to nearly the boiling point. Our own idea of evaporation has always been, that there should be the largest possible surface of liquid exposed directly to the air, in order to get the best results.

The air acts as a sponge to suck up the fluid, so to speak. It is well known that evaporation goes on most rapidly when the atmosphere is dry, and when a current of air passes over the surface of the fluid. In the apparatus here proposed, a moist atmosphere, or rather pure steam is constantly over the boiling liquid. On further considering the subject, we are inclined to think the amount of heat saved in barely bringing the cold sap to a boiling heat would hardly repay the loss incurred in evaporating under cover. We may perhaps be in error. A practical test would be to evaporate a certain amount of sap, with the cover on, and the same quantity with it off, and compare the amount of fuel consumed.

Cheap and Good Straw Hives.

E. J. Ferris, of Lake Co., O., J. T. Smith, of Unlontown, and several others, inquire how to make the straw hives referred to in the July *Agriculturist*. While at M. Quinby's, we examined quite a variety of straw hives, mostly patented by different parties. We will describe one of the best forms, one which is unpatented, and can be made by any person with moderate skill. The size depends upon what is required. If for a particular kind of honey-boxes or movable frames, the size must be

Fig. 1.—FRAME FOR THE STRAW.

made to correspond with what is wanted. It is a square or parallelogram, to be covered with a flat board to receive the surplus boxes, and over this a wooden box with sloping or flat roof, and projecting over the sides to shed rain. The essential part or body of the hive is made as follows: For the upright corner-pieces, cut 2-inch square stuff to the required length.

Upon the *inside* of these nail three pieces of lath for the sides and ends, putting one strip around both top and bottom, and one in the middle, as seen in fig. 1. Then nail flat thin strips, 2 inches wide, around the top and bottom, covering the ends of the uprights, as also shown in fig. 1. Next cut clean, straight straw, in a cutting-box, to just the required length to fit into the sides. Pack this straw in firmly upon the sides, and nail strips of lath on the outside, as shown in fig. 2, and the thing is done. To prevent crowding off the inside strips while packing in the straw, it is well to have a false box just the size of the inside, and slip this in while packing the straw. To prevent the spreading of the lath, bind them together at the middle points with wire running through the straw, especially on the longer sides of the hive. Straw hives are grateful to bees, cool in Summer and warm in Winter, and with the straw standing perpendicular, as above described, it sheds off all rain. As 2 inches thickness of straw would seem to be more than is needed, if the corner-pieces be 2-inch stuff the outside slats might be

Fig. 2.—THE STRAW FRAME COMPLETED.

let into the pieces the depth of their thickness, though this would somewhat increase the labor of making them. They are quickly and cheaply made, and are neat in appearance, especially if the wood be planed; this is not essential, however. If the wood-work be painted, they will look still more attractive.

For the *American Agriculturist*.

A Cure for the Sorrel.

The death of this pest would be hailed with as great joy as that of poor Cock Robin was with grief. The bull could afford to pull the bell that rang its death knell, for henceforth hay would be more plentiful in many a scanty meadow. But it is not dead, as the meadows with their large red patches testify. It is found not only in the fields of the slothful, but in those of the diligent. To be sure it is most abundant on the former, Mr. Slack descants upon the adhesive qualities of sorrel thus: "It is of no use to try to get rid of it. It is one of those things that is doomed to come. Wan't weeds a part of the curse upon the soil? What is to be, will be, and there is no use in fighting against nature." Slack is provoked at any complimentary allusion to the ruddy aspect of his fields. Pray don't sorrel grow every where? Not exactly every where. It is found in great abundance on old meadows where the grass begins to fail. The philosophy of this fact may be that the grass has sucked out all the aliment in the soil suited to its nature, and the sorrel comes in as a succession crop. It is worthy of notice that sorrel abounds in soils that have been long manured with uncomposted fish. This manure stimulates the land to a large production of cereals, and when it is laid down to

grass, it very soon relapses into sorrel. It also comes in extraordinary quantities upon reclaimed swamp land imperfectly drained.

Now the remedy I have to propose for sorrel, is an old fashioned one, and requires money and labor. Apply manure either as a top dressing or for hoed crops. Every farmer must have observed that sorrel is not troublesome upon a rich, newly seeded meadow. The clover overshadows it, if it undertakes to grow, and the herds-grass and other grasses obscure it for several years. The sorrel is only a gentle hint from nature, that the last grist of manure put into her hopper is ground out, and needs to be resupplied. You can have fodder only as you keep the hopper full. If the soil is wet, there is no effectual remedy but in drainage. In upland meadows the manure will last several years. When the sorrel reappears, apply manure, and if the grass is feeble, sow grass seed at the same time.

CONNECTICUT.

Tim Bunker on Starting a Sugar Mill.

"Who'd have thought of ever seeing a sugar mill in Hookertown!" exclaimed Seth Twiggs as he looked at that new institution just put up on the Shadtown road.

"And such lots of sorghum too," said Deacon Smith. "Almost every farmer has a patch."

"The age of meracles ain't past yet," said Tucker in a meditative mood.

"I wonder if there'll be any rum made of the leavings," inquired Jones expectantly, recalling his experience on a sugar plantation.

"Not a bit of it," said Seth, with a twinkle in his eye and an extra puff at his pipe. "Suckers will go dry in these parts."

Ten years ago, I should as soon have thought of seeing an elephant in my barn yard, as of seeing a sugar mill in Hookertown. In the first place there was nothing to make sugar of, except a few maple trees, and they did not require a mill. And then there was not enterprise enough to start a new project of that magnitude. We, most of us, believe in foreordination and had not put down sugar making as among the things that were destined for Hookertown. We expected always to get our sweetening by barter, just as our fathers and mothers did before us—a pound of cheese for a pound of sugar, and brown sugar at that. We expected too to eat a slave-grown article because we could not get any other. But they say they are getting off the notion of forced labor on the sugar plantations, in Louisiana, and I suppose when the States got to making a change, they thought they might as well make a change all around, and have free sugar North and South. At any rate it is a settled fact, that we have a sugar mill, where they are going to make molasses this Fall, and where they may make sugar by and by. I suppose half the farmers in town won't pay a dollar for sweetening next year, and some will have a few barrels of syrup to sell. The world moves, notwithstanding the war, and I am not sure but the war has given a good many enterprises a new hoist. You see it has made sugar and molasses dear, and that has set Yankee wit at work to get these things out of our own soil. In raising sugar at the North, it makes a great deal of difference whether that article is eight cents or sixteen cents a pound.

We have been getting ready for this business some years. The seed sent out from the *Agriculturist* office, introduced the plant, and taught us that we could grow it as well as corn. Jake Frink could see that it looked like broom

corn, and was no humbug. It would pay to raise it for fodder for cattle, and hogs ate it greedily, and would thrive upon it wonderfully well. There was no chance to lose much. Some made syrup from it, the first year, and put it up in bottles, and exhibited it at the county fair. It looked like syrup, tasted like it, and went well on buckwheat cakes. But we had no mill to grind the cane, and no conveniences for boiling down the juice, and that was the great objection to going into the business.

Last Winter we talked the matter up in the Farmers' club. Men in whose judgment we had confidence, said the thing would pay. Mr. Spooner, who is ready for every good word and work, said there was no good reason why we should not make our own sweetening, at home; that the farmers in the town paid out twenty thousand dollars every year for this article, and they might just as well keep that amount in their own pockets. Deacon Smith read extracts from the agricultural papers, showing what they were doing out West, raising two and three hundred gallons of syrup to the acre, and clearing over a hundred dollars above working expenses. He said the crop last year was worth several millions of dollars, and that the business was increasing rapidly wherever they had learned to make the syrup.

Seth Twiggs said they had started a mill at Smithtown, and it worked well. He brought along several bottles of the syrup made at the mill, and to convince the skeptical, sent it around for trial. It was found that it made good gingerbread, it sweetened coffee, and filled the place of molasses completely. After a fair trial, and several weeks talking, in which every man made sure that the syrup would not bite, we got the club up to the question—"Shall Hookertown have a sugar mill?" This was the name the thing seemed to take of itself, though I suppose they will make nothing but syrup at present. It was agreed that the syrup was the thing we all wanted, and we were all ready to go into it if the thing could be made to pay. Two men agreed to build the mill, and put into it every thing necessary to grind the cane and boil the syrup, if they could have cane enough to make it an object. They wanted three hundred acres pledged. This, with what they raised themselves, they thought would make it a safe enterprise.

To get the cane pledged in a community of small farmers, many of them not having more than ten acres under the plow, was a good deal of an undertaking. It was agreed to appoint a committee for each school district, to see how much could be raised. There were fifteen districts in the town, and it would take about twenty acres to each district. Mr. Spooner took the matter in hand in his district, and worked as hard as any of us. Some subscribed two acres, and some a half acre. We raised about three quarters of the pledges here, and for the rest we had to go to Shadtown.

The results of the Winter's work are, that we have a wonderful increase of sorghum in all this region. A patch may be found on all the best farms and on some of the poor ones, and even in the gardens of the mechanics. A quarter of an acre of sorghum will make a barrel of syrup, if it does only moderately well. We shall not have syrup enough to supply the town, perhaps, but we shall give the business a good start, and wake up the sleepers. I should not think it strange if we became exporters of syrup in a few years, and Connecticut syrup may yet stand as high in the market, as Connecticut River shad. The mill is all up, and the

machinery in, and they will be ready to grind as soon as the cane is fit. I do not see any reason why New England should not raise its own molasses. We have plenty of unoccupied land, and capital to invest in the crop, and in mills to manufacture it. All that is needed, is a few individuals in each town to talk the matter up, and show how it can be done. There must be concert of action, and then the whole business will go easy. The sorghum is coming into favor much more rapidly than the potato did, and it would not be strange if it wrought as great changes in our husbandry.

Hookertown, } Yours to command,
Sept. 10th, 1863. } TIMOTHY BUNKER ESQ.

Gift Enterprises and Other Humbugs.

We had supposed that the "Gift Enterprise" business was about "played out" in this country, since the frequent and thorough exposures of the knavish character of the business, which have from time to time appeared in the *Agriculturist*, and various other journals. Occasionally however, we receive a circular indicating that there are yet parties ready to be duped by golden promises, and rogues prepared to take advantage of their ignorance. One of these programmes is now before us. It dates from a "National Art Gallery," and proposes to sell "Twelve Magnificent Steel Plate Engravings," at the low price of *One Dollar* each, and to furnish with each engraving a valuable gift, valued at from 50 cents to \$100. In addition to all this, 50 United States Bonds of \$100 each are offered as additional premiums, and "as each print will have a limited issue of less than ten thousand copies, these Bonds must soon be distributed." In what manner the distribution is to be made, is not stated. As the "fools are not all dead" yet, we suppose some investments will be made by those who have not already been "bitten" by the same operator.

"Honor among thieves" has long since passed into a proverb, but its fallacy is being continually shown. A recently exposed swindle is in point. Letters marked "strictly private" were received by numerous parties, in which the writer proposed to sell them gold coins of the denomination of \$1, at 50 cents each. They were warranted to be such complete imitations of the genuine, as to defy detection; not even the banks would refuse them. None but a rogue, or a man of very weak honesty, would bite at such a bait, but the temptation proved too strong for many, who forwarded the dollar, and received their coins in return. As was promised, they readily passed as genuine, "even at the banks." Elated with their success, the dupes speedily sent larger amounts, from \$5 to \$25 for more coins, but they could get no replies. It turned out that the specimens first sent as a bait, were genuine coin, but the rascal appropriated all additional remittances, rightly judging that parties attempting to purchase counterfeit money, would be in no haste to complain of the swindle to the authorities. Ultimately, however, the matter was brought to light, and the ingenious operator is now in confinement awaiting his trial. He deserves punishment for holding out the temptation to the unwary, of making money dishonestly. The rule heretofore given needs to be often repeated, viz.: *avoid dealing with all parties who offer to give more than a dollar's worth, for a hundred cents.* They can not continue to fulfill such contracts without dishonesty to some one, and the loss will usually fall upon those who are caught by splendid offers in circulars and advertisements.

Useful Rules for Measurement.

I submit for the benefit of readers of the *American Agriculturist* a few rules for ascertaining the capacity of vessels, and for the measurement of solids of the descriptions named. It is unnecessary to state their importance to all who have to measure grain and other produce, and the necessity of being able to estimate accurately the capacity of vessels temporarily made, as well as those permanently used; and as it is well known that very many of those who are passing large quantities of goods of all sorts through their hands daily, do not know how to ascertain the correctness of the capacity of the vessels they are in the habit of using, and may therefore unknowingly cheat or be cheated, the necessity of such a knowledge is evident.

1.—To find the cubical contents of rectangular vessels.

RULE.—Multiply the length by the width and height.

Example.—What is the cubical contents of a vessel 30 inches long, 30 inches wide, and 60 inches high?
 $30 \times 30 \times 60 = 54,000$ cubic inches, *answer*.

2.—To find the cubical contents of cylindrical vessels.

RULE.—Multiply the square of the diameter by .7854, and the product by the height.

Example.—What is the cubical contents of a vessel 30 inches diameter and 60 inches high? *answer*.
 $30 \times 30 = 900 \times .7854 = 706.86 \times 60 = 42,411.6$ cubic inches.

3.—To find the cubical contents of rectangular tapered vessels, mathematically called prismoids and frustums of a pyramid: used for agricultural purposes in weigh-hoppers, etc.

RULE.—To the sum of the area of the two ends add four times the area of the middle in a line parallel to the base, and multiply this sum by one-sixth of the perpendicular height.

Example.—What is the cubical contents of a vessel 60 inches high, 21 inches square at the top, and 40 inches square at the bottom?

$20 \times 20 = 400$, area of top.
 $40 \times 40 = 1600$, area of bottom.
 $4 \times 30 \times 30 = 3600$, four times area of middle. *answer*.
 5600×10 , (one-sixth of the height,) = 56,000.

4.—To find the cubical contents of round tapered vessels, (frustums of cones.)

RULE.—To the sum of the square of the diameter of the two ends add four times the square of the diameter of the middle: multiply this sum by .1309, and the product by the perpendicular height.

Example.—What is the cubical contents of a vessel 20 inches diameter at the top, 40 inches diameter at bottom, and 60 inches perpendicular height?

$20 \times 20 = 400$, square of top diameter.
 $40 \times 40 = 1600$, square of bottom diameter.
 $4 \times 30 \times 30 = 3600$, four times square of middle diameter.
 $5600 \times .1309 = 733.04 \times 60 = 43,982.4$, *answer*.

In the 3rd and 4th examples, the middle diameter or distance across is obtained by adding the diameter of the top and bottom together, and dividing the amount by 2.

A bushel contains 2150.42 cubic inches, 1.244 or nearly $1\frac{1}{4}$ cubic feet, or 9.31 gallons. A gallon contains 231 cubic inches, and there is therefore 7.48 or nearly $7\frac{1}{2}$ gallons in a cubic foot. Hence, dividing the number of cubic inches contained in a vessel by 231, we find the number of gallons; or, dividing by 2150.42, we have the number of bushels it contains. Or if the contents of the vessel is given in cubic feet, then, by multiplying them by 7.48, (or $7\frac{1}{2}$), we find the number of gallons; dividing by 1.244, (or $1\frac{1}{4}$), gives the number of bushels it contains. As, however, there are many men who can easily do the first four rules in arithmetic, but are puzzled at, or altogether unable to work out decimals, I subjoin the two following rules by which they may find out the number of gallons or bushels a vessel contains, without the use of decimals. These rules, it will be observed, are only for the calculation of gallons and bushels in round vessels; for their actual cubical contents, they must be worked out by the first four rules.

5.—To find the number of gallons and bushels in a cylindrical vessel with parallel sides, as, for example, a bushel measure.

RULE.—Multiply the square of the diameter in inches

by the height in inches, and divide the product by 294 for gallons, or by 2738 for bushels.

Example.—What is the number of gallons and bushels contained in a vessel 30 inches diameter and 60 inch high?
 $30 \times 30 = 900 \times 60 = 54,000 \div 294 = 183\frac{3}{4}$ gallons, and
 $54,000 \div 2738 = 19.7$ bushels, *answer*.

6.—To find the number of gallons and bushels contained in round taper vessels.

RULE.—To the sum of the square of the diameter of the two ends add four times the square of the diameter of the middle: multiply this sum by the height, (all in inches,) and divide the product by 1764 for gallons, or by 16,428 for bushels.

Example.—How many gallons and bushels are contained in a vessel 20 inches diameter at top, 40 inches diameter at bottom, and 60 inches perpendicular height?
 $20 \times 20 = 400$, square of the top diameter.
 $40 \times 40 = 1600$, square of bottom diameter.
 $4 \times 30 \times 30 = 3600$, four times square of middle diameter.
 $5600 \times 60 = 336,000 \div 1764 = 190\frac{1}{4}$ gallons, and
 $336,000 \div 16428 = 20.4$ bushels, *answer*.

Although as has been remarked, the 5th and 6th rules are to facilitate the calculations of the description of vessels named, by those who do not understand decimals, it will be apparent at a glance that they are simple, and useful to all who have such calculations to make.

A similarity in the whole of the examples given will be observed. This is done to enable a comparison to be made in the contents of vessels of similar sizes, but of different shapes.

Schenectady Co., N. Y.

WM. TOSIACIL.

For the American Agriculturist.

A Clay Soil no Curse.

How often do farmers whose lands are clayey, complain of their hard, stiff soils, so inclined to be cold and wet in Spring, baked hard in Summer, and tedious to work at all times! Very well, these are bugbears to shiftless farmers, but not so to enterprising men. Wet and cold in Spring? Shows they need draining. Baked stiff in Summer? Shows they need manuring and diligent working. Tedious to till at all times? Yes, very likely, more toilsome than sandy land; but then how much more productive and durable. In his "Principles of Agriculture," Thaez says: "Land should be chiefly valued according to its consistence; the greater the degree of this quality which it possesses, the nearer does it approach to first class land; but the smaller the proportion of clay, and the larger the quantity of sand which enters into its composition, the more rapidly does it fall in value." What say Jersey and Long Island farmers to that? What say the Arab farmers to the value of their shifting sands? Are not the clay lands of old England the most productive that the world has ever seen? Clay, if not mixed with foreign and noxious ingredients, contains in itself elements of fertility. It holds the rich deposits of many ages, which only need bringing to the influence of air and tillage to make them yield their riches to the cultivator.

Moreover, clay is very retentive of all manures applied to it, while sand soon leaches them away. How often do we hear the owners of sandy farms complain in this wise: "Oh! it's just like putting water into a sieve!" Sandy soils are easier to work, but in the long run the clays are usually most productive. Some very interesting results have been achieved by dressing sandy soils with clay, the clay seeming to add positive fertility, as well as to increase its consistency. But in the question between clay and sandy land, probably all will agree that the best soil lies between the two extremes, a clayey loam being better for all ordinary purposes than either pure clay or pure sand. Z.

[There is no doubt that clay lands, if rightly treated, are the best, unless entirely made up of tough brick clay. Plants need a bed of fine

earth for their delicate roots to flourish in. A clay soil, well drained and deeply broken, furnishes this bed. Remove all surplus moisture by thorough drainage, then turn up the soil deeply for the action of air and frost, and you have just the kind of land that will bear good crops, and last forever. If devoid of sand enough to make it friable, a good mixture of muck, manure, sod turned under, or other vegetable matter, will help to ameliorate it. Were we hunting a farm to-day, we should choose a stiff soil, investing only a part of the capital in the soil, and using the rest to put it into good condition—for the same reason that we would buy one good machine rather than two poor ones.—Ed.]

Pedigree in Plants.

The general superiority of *blooded* animals, that is, those whose pedigree can be traced through families possessing marked and fixed points of excellence, is now generally conceded. It is acknowledged that an equal number of the Durhams, Devons, and Herefords, among cattle, of Merinoes, Southdowns, and Cotswolds, among sheep, etc., will, as a class, show superior qualities to the miscellaneous stock known as natives. But the same principle of superiority from breeding among plants, has not yet been as fully recognized. Yet there is abundant reason for supposing that the same law is equally prevalent in the vegetable as in the animal kingdom; that "like begets like," and that observance of this law may be turned to most profitable account by cultivators. To some extent this is acted upon, in saving the best seeds of grain and other products, but it is only recently that definite experiments have indicated how great improvement can be realized by proper and continued selection of seed. The experimental researches and success of Mr. F. F. Hallett, of Brighton, England, have already been noticed in the *Agriculturist*. New interest has been excited in this subject recently by a meeting of a large number of the leading farmers of England, to inspect his farm and witness the progress of his operations. From year to year this gentleman has selected, not only the best heads of wheat, but the best kernels of the finest ears, and used them for seed. One of the visitors says, "two or three features in the appearance of the wheat fields forcibly struck us, namely, the extraordinary strength of the stems which enabled them to withstand a very severe storm occurring July 21st, and maintain their upright position; the uniform size of the ear, and the absence of 'under-corn' (dwarfed wheat). We counted on one stool 42 ears, all of which were of the same size and as near as possible, of equal height." In reply to the question, "What was the average product of his wheat crop last year?" Mr. Hallett said he should keep far within the limits of truth in stating that the *maximum* was six quarters (48 bushels per acre), and the *minimum* four and-a-half quarters (36 bushels) per acre. He also gave three instances which had come to his knowledge, of large productiveness of the improved wheat, which yielded respectively, 72 bushels, 62 bushels, and 60 bushels per acre.—Now what has been done in England, can be repeated here. No one can fix the limits to which productiveness may be carried by following out similar experiments. May we not hope in a few years to find improved "breeds" of wheat, of corn, and other cereals in this country, as well marked, as are the established strains of horses and cattle?

AUTUMN SCENE—SECURING THE INDIAN CORN HARVEST.

The scene represented above is peculiarly American. Nowhere else does the maize plant add beauty to the landscape, and abundance to the resources of the Nation. In other lands, the failure of Wheat is followed by scarcity of food, and suffering among the poorer classes. In many sections of our own country, Indian corn is the principal dependence for human food, and in case of necessity it can be generally substituted for other cereals, as has been repeatedly done in sections where the wheat and rye crops have come short of the demand. It is the abundance of corn and its excellence as an article of food, that enables us yearly to export such immense quantities of other grain to foreign lands. To this staple, as much, if not more than to any other one production, is our national prosperity due. Without it as cheap food for their laborers, the cotton planters could never have made the production of their favorite crop a paying operation. If ever cotton was "King," maize was "Prime Minister," and has now worthily succeeded to the throne, even in the South. For beauty of appearance no cultivated plant may better claim such honor. Its stately form, clad in garments of fairest green, gracefully bearing aloft a jeweled scepter, and bedecked with golden crown, proclaims its royal prerogative. Nor is the smile altogether fanciful when its habits are regarded. It must live upon the fat of the land. The richest stores of the farm must be laid at its feet; from infancy to maturity

it will brook no neglect. But unlike too many sovereigns it makes grateful return for the homage it exacts from its dependents. The general crop during the present year, though not as large as has been gathered heretofore, from early and recent unfavorable weather, is yet a fair one—enough to supply the home demand, and leave a large surplus for export.

Much loss is experienced every year from neglect of the corn crop after it is ready for harvesting. As we have frequently said, cutting up by the ground is every way preferable for most sections. Care is required in curing the stalks. If the stooks are made too large, or carelessly put up, they may heat, or be soaked with rain, and mould, and much of the corn be spoiled. If the corn is to be husked directly from the stalk as standing in the field, it is desirable to have it completed as early as practicable; otherwise the birds, mice, and other depredators will take a large toll. We have seen the golden ears peering from a wreath of snow in Winter, having been left uncared for, except by vermin; such management, it need not be said, is not the most profitable farming. The first fruits of the crop should be gathered for seed, carefully selecting the best ears from the most prolific stalks. These should be carefully trussed together by braiding the husks, and hung where they will thoroughly dry before freezing; much seed corn is spoiled by neglect in this particular. After the corn is removed

from the ground, it is desirable that the remaining stumps be broken down before plowing for the following crop; otherwise they remain a vexatious impediment to cultivation. This can be done by drawing a roller or a rough stick of timber across the field when the ground is frozen.

How are you Marketing your Fruit?

Fruit can be knocked from the trees by shaking, by beating the limbs with long poles, and by other rough ways; it can be picked up in baskets and dumped into a wagon box, and taken to the nearest village and sold—at a very low price. By this treatment good fruit can be rendered nearly worthless, or at least fit only for immediate use, while the same fruit carefully picked and properly packed, would bring a price enough higher to amply repay all the extra care of preparation. We may say with truth, that a bruised apple is a spoiled apple. An apple which would last for months, will, after it gets a slight bruise in falling, soon decay and become worthless. The first thing to be attended to in marketing fruit, is the picking. Hand picking and careful handling—as careful as if the fruit were eggs—is absolutely necessary if we would get good fruit to market in good order. If the trees have been properly trained with low branches, most of the fruit may be reached by some kind of a self-supporting ladder, and there are several fruit-pickers which

may be advantageously used to reach those otherwise inaccessible. If the fruit is to be disposed of at the nearest market town, it will pay to use care in picking, but if it is to be consigned to a distant city, it is absolutely necessary to do so. During the first week or two after it is taken from the tree, fruit loses a considerable amount of moisture, or "sweats," as it is termed, and it is necessary that this process should be through with before packing. The "sweating" may be done upon a barn floor, or the fruit may be put in heaps in the orchard and covered with straw if there be danger of frost. Fruit should be kept at an even temperature, and as cool as possible without freezing. From the time that fruit is mature it constantly tends to decay, and that state in which we say the fruit is "in eating" is one step toward decay. The process can be made to go on slowly, or be retarded almost indefinitely, by keeping the fruit at a sufficiently low temperature. After the fruit has gone through the sweating process, it should be barrelled. It is better to make two grades of quality, separating the finest from those less large and fair. A few poor looking apples will injure the sale of a barrel of otherwise first class fruit. Never mix sorts, even if they closely resemble each other, and mark each barrel with the name of the fruit. It is of the greatest importance that the packing should be so done that the fruit will not shake about and bruise one another in carriage. The use of packing material is now generally abandoned, at least for apples, but the fruit is pressed into the barrel so strongly that shaking is prevented. The head may be pressed down by means of a lever, as shown on page 9 of the January *Agriculturist* for 1861. A convenient screw-press for the same purpose is sold at agricultural ware-houses.

Strawberries and Other Small Fruits at the West.

Mr. S. S. White, Mercer Co., Ill., sends to the *Am. Agriculturist* his experience with small fruits, which we give for the benefit of our western readers. He finds "Hovey's Seedling (well fertilized) worthless. Wilson's Albany suffered most from drouth. Burr's New Pine, and three other Pines are small, but the fruit sweet. Triomphe de Gand does not bear as well here as at the East, but the fruit is large, and the flavor very good. The Hudson, an old market berry, has been more prolific with me, and bears the drouth better than any other variety; the berry is firm and the flavor reasonably good. I shall discard all the varieties I have tried or seen tried in the West, except Triomphe de Gand, Wilson's Albany, Hudson, and Austin."

Mr. W. thinks that our directions for planting in narrow beds will not answer for the West, where land is plenty and labor scarce. He makes his plots of the dimensions of a quarter of an acre, manures well, and plows deeply. He then, by the aid of a line stretched across the plot, puts the plants out 12 to 15 inches apart in the rows, and sets the rows at three feet apart. "To dress the bed, use the cultivator early in the Spring twice, and two or three times after the vines have done fruiting. If no cultivator is at hand, use the small double-shovel corn plow. A man or boy will go over a quarter of an acre in an hour, and brush off with his hand the dirt from such plants as may get covered. Expense of work with cultivator \$2; hire of girl 6 days to elip runners \$2; pulling weeds in rows, the season \$1. Whole necessary expense of culture \$5. Yield of berries, 25 to 40 bush-

els on a quarter of an acre plot, according as the season is wet or dry." Mr. White advises his western friends not to be content with the strawberry alone, but to grow other small fruits. Houghton's Seedling Gooseberry, and the New Rochelle blackberry have done finely with him. The Hudson River Antwerp is the only good variety of Raspberry that will stand the winter in his locality without covering. Letters of the character of Mr. White's are always acceptable; though we may not publish them, they are of use in enabling us to judge what varieties are best adapted to particular States and localities.

Leadene Labels for Fruit Trees.

A friend, who modestly wishes to be known as "Ignoramus," having read a note in the July *Agriculturist* upon the importance of looking to the tree labels, sends us a device which he uses, and one which may in many cases be worthy of being adopted. The engraving represent his fruit label. It is a strip cut from common sheet lead, half an

inch wide at one end, and gradually tapering to a point. Strips can be cut to this wedge form from a wide strip, without waste. Near the broad end a number, corresponding to that on a catalogue, is either stamped or cut with a knife. Just beyond the number a hole is made with a square punch or nail-set, and the small end of the label is put through this and bent over to fasten it. This appears to be a feasible plan, and one which will be found useful where there are a large number of trees to label. Should a label be thrown off by the expanding of a limb, or from other causes, being of lead, it will not be blown away and lost, as a wooden one might be.

A New Melon—The White Japanese.

This superior fruit was first introduced to the public by the enterprising horticulturist, Wm. S. Carpenter, Esq. We understand that the seed was brought to this country by some member of Com. Perry's Japan Expedition.

Fig. 1.—OUTSIDE OF MELON.

Though this variety has been known to a few cultivators for some years, it is to most people quite new. We have grown it for two years and are so well satisfied with it, that we are desirous that our readers should be on the look-out for it,

as the seed will soon be so generally distributed as to be readily attainable. Fig. 1, represents the general shape of the fruit, which is usually globular, though some times it is slightly oblong. The furrows are very shallow and the surface but sparingly netted. The color is one of its most remarkable characteristics, being nearly

Fig. 2.—INSIDE OF MELON.

white, or at least, a greenish white. The flesh, which is very thick in proportion to the size of the melon, is greenish, tinged with orange. When well ripened, the whole flesh is eatable, the rind being scarcely thicker than the skin of an apple. The texture, sweetness, and flavor of the flesh are all that can be desired. We know that tastes differ with regard to melons, as they do with respect to other fruits, and can only say that this new variety pleases us. It is a prolific bearer, and we hope to see it introduced in place of many inferior kinds now cultivated.

How to Raise Seedling Tree Stocks.

H. K. Ackerman and others ask us to give some hints upon planting seeds for the purpose of raising nursery stocks. This is a matter which is generally left to the professional nurseryman, but there is no mystery about it, and any one who cultivates fruit can readily raise his own stocks. The soil for the seed-beds should be finely pulverized and well fertilized with old manure. The young seedlings need a tolerably rich soil to give them a good start and insure a vigorous growth the first season. Good clean and well-grown wood is essential to success, whether the stocks are budded or grafted. The seeds should be secured in the Fall. In this country it is customary to take the sound seeds of any variety, and for apples, the pommace left after making cider, is usually resorted to for obtaining seeds. In the family where much fruit is eaten, a quantity of seeds can be saved daily, if each one, after eating an apple, peach, or pear, will take the pains to preserve the seeds. A box or common flower-pot of sand should be kept standing in a convenient place, where each one can deposit the seeds from the fruit he eats. Where pommace is used, the seeds are separated by washing, collected, and dried, and then sown at once, or put into boxes with very slightly damped sand, and kept until Spring. If fruit is chosen expressly for the seeds, it is allowed to decay until the seeds can be readily separated. It is altogether best to sow in the Fall, if possible. If a large quantity is to be planted, it is best to make the drills about three feet apart, in order to allow the use of the cultivator, but if the bed be small, the rows may be at a convenient distance to work with a hoe. Having stretched a line &

mark the row, open a trench with a hoe, about three inches deep, and distribute the seed as evenly as possible. Then cover with soil to the depth of three inches. A thin layer of old and well-decomposed manure spread over the rows will be of advantage. This is the usual way of planting apple and pear seeds. Pear stocks, however, need rather more care than the apple. Every means should be taken to hasten the early Spring growth, and a liberal supply of ashes to the soil will be found beneficial, and, unless in a limestone country, a good supply of lime should be given to the soil. When the seeds start in the Spring, the plants should be thinned out so that they will not crowd one another, and the growth promoted by frequent cultivation and weeding. In thinning, leave the most vigorous looking plants. In Autumn the seedlings are to be taken up, with care not to injure the roots. They are to be cut back, both at the top and roots, from one-third to one-half. Those large enough for root-grafting are placed by themselves, and the weaker seedlings are put together to be planted out in the Spring, to make another growth. Both sizes are to be preserved in slightly damp sand or earth in the cellar. During the Winter, the grafting may be done, and all be ready to put out in nursery rows as soon as the ground is fit to receive them. Cherry stones may be treated in the same way. Keep them in boxes of sand until Autumn, and then plant. In collecting peach pits for stocks, we cannot too often repeat the necessity of securing them from perfectly healthy trees. The pits may be kept in boxes, mixed with sand or earth, and exposed to the full influence of the frost; or if the quantity is large, they may be mixed with earth, and made into a mound well covered with soil, in a convenient place. When the germ shows signs of starting in the Spring, the seeds may be planted with a dibble in nursery rows. By the following Autumn the seedlings will usually be large enough for budding.

For the American Agriculturist.

Currants and How to Propagate Them.

Communicated by an Experienced Cultivator.

The Currant is one of those fruits which seem to thrive in spite of neglect, and to give tolerable crops in almost any soil and location. They will grow and produce some fruit if the bushes are allowed to have their own way and are choked with weeds. Let any one compare the fruit as ordinarily produced, with the fine specimens which have been shown on the tables at the *American Agriculturist* Office, and he will see that there is something to learn, even about currants. Any sort properly cultivated and pruned, will give far better fruit than it will if neglected, and there are new and fine sorts, requiring no more care than the old ones, which will produce fruit vastly superior. For red sorts, the Cherry and La Versailles, and for white, the White Grape and Provence, will give a good selection, though there are many others which have their advocates. The sorts in cultivation are generally of foreign origin, but some native species have lately been introduced from the far West, of which we have great hopes. For the present, however, we must be content with the European sorts. There is, perhaps, no plant more easily propagated than the currant. During the present month (October) select strong wood of last year's growth, and make cuttings of six inches to a foot long, cutting them off just below a bud, and square across. To pre-

pare the cuttings for planting, cut out every eye or bud except two or three from the upper end. Cuttings may be planted and grow without all this trouble, but if good tree-like plants are desired it is necessary to take some pains to procure them. Stretch a line across the bed where the cuttings are to be planted, and then take a spade, place its back against the line, force it into the ground nearly perpendicularly to the depth of about six inches, and throw out the soil, thus making a trench the shape of a letter V. Now set the cuttings about three inches apart, along in this trench, with their upper ends about even with the surface, as the soil will settle enough during the Winter to expose the upper buds. Throw a little soil into the trench, just enough to cover the lower part of the cuttings for one or two inches, and then with the handle of the spade, or the edge of a piece of board, crowd the soil down firmly around them. It is essential to success to bring the soil closely in contact with the freshly-cut portion, so as to exclude the air. If the cuttings are set in the latter part of September, or early in October, they will often become well rooted by Winter, and be prepared to make a vigorous growth in Spring; indeed they will do twice as well as cuttings put out in Spring. When cold weather comes on, the cuttings should have a covering of three or four inches of leaves or straw, not so much to keep out the frost, as to prevent them from being thrown out by frequent freezing and thawing. In the Spring the covering may be removed altogether, or it may be parted just over the cuttings, and left as a mulch. The soil for cuttings should be well worked; only old, fine manure be used, and a dry situation should be selected for the bed.

Healthfulness of Currants.

Mrs. W. Hauff, Richmond Co., N. Y., in a communication to the *American Agriculturist* says: "Whenever I see the abundant planting of currants recommended by you, I feel as if I must tell you that I have found this excellent fruit a sure preventive of dyspepsia. For three summers past I have made my breakfast of them as long as they were to be had, and eaten them frequently during the day besides. I find that a plateful of currants eaten with sugar in the morning, disposes of all the bad accumulations in the stomach, without giving diarrhoea, and helps to strengthen the digestive power through the wholesome acid this fruit contains, in which it is superior to the strawberry, raspberry, etc., for I have tried each in its turn. I can digest, without trouble, a hearty dinner after I have had a breakfast of currants, while at times my stomach has been so weak, that a cup full of broth or soup only, would give me pain as if a cancer was gnawing within me."—[This accords with the experience of many others, but in the treatment of dyspepsia, or any other disease, it should be borne in mind that "what is one man's meat, is another's poison." Each must experiment and determine for himself what is suited to his particular case. In general, however, it may be safely asserted that a more liberal use of this and other fruits during Summer, in place of meat, would greatly diminish dyspepsia and other ailments of the digestive organs.—It is to be remembered, however, that when currants are eaten, every berry is to be broken, before it is swallowed; the gastric juice of the stomach can not act upon the unbroken skin, and whole currants produce irritation through the whole alimentary canal, often caus-

ing colic and diarrhoea. Children and persons having defective teeth, too often swallow them unmasticated, and suffer therefore.—Ed.]

Renovation of Fruit Trees.

Mr. Wm. H. Morgan, of Harford Co., Md., writes to the *Agriculturist*: "I had a fine large apple tree which was very thrifty, but did not bear in the Spring. I dug a ditch just under the outer ends of the limbs, cutting off all the ends of the roots; and some months before the leaves of the other trees faded, this tree's leaves turned yellow. That Fall I manured the ground heavily, and in the following Spring strewn a peck of bone-dust over it, and plowed it in, and then put on a half bushel of ashes. This season the tree looks very flourishing, and has half a crop of apples upon it, while before it scarcely ever yielded a dozen, and they were small and knotty. Others of my trees which I treated in like manner, except cutting off the roots, have borne full this season."

Manuring Fruit Trees Injurious.

An indignant subscriber writes us that, in accordance with the advice of this paper, he dressed his young fruit-trees last Fall with horse manure, forking in the same the following Spring, but that his trees were injured by it. They did not put forth leaves until June, and then only after he removed the manure, headed them back severely, washed the trunks, soaked the ground, etc.

Did we ever advise to apply "horse-dung," and that in a fresh or decomposed state, as we learn yours was? Well-rotted manure, cow and horse dung together, composted with muck or sods, would be nearer to our doctrine. We have often said, and now repeat it, that perhaps the safest and best fertilizer for young trees, both fruit and ornamental, is swamp muck composted with lime at the rate of two bushels to the cord evenly distributed through it, or of ashes at the rate of about six bushels. This should lie in a heap several months, and be forked and shoveled well together several times. And when used, it will do no such harm as did our friend's hot horse dung. It will keep the soil healthfully moist in Summer, porous and sweet at all times, and will furnish vegetable food for the roots in a gradual way, just as they need it. A little old dung mixed with it will do no harm. And when applying it, let it be spread over the entire surface of the roots, not in a heap close to the trunk of the tree.

What Early Apples to Plant.

Several letters have been sent to the *Agriculturist* office asking advice as to early varieties of apples, but no letter has stated whether they were to be grown for market or for home consumption. Those who prefer a moderate quantity of choice fruit for their own use, would require a different selection from those who wished to get the most for their fruit in the market. As the best summer kinds we name: Primate, Gravenstein, Early Joe, Red Astrachan, Summer Queen, and Yellow Sweet Bough; the last three being best adapted for marketing. The Primate is an apple which will give general satisfaction and is in some places cultivated as the Early Bough, and Early Harvest, to both of which it is greatly superior. Gravenstein is a remarkably high flavored fruit, and the Early Joe is probably the best of all early apples. It

is small, but for quality we have not seen it surpassed. The Red Astrachan and Summer Queen are both showy apples, of fair quality, and their appearance causes them to bring a good price. We are the better pleased with the Summer Queen, the more we see of it. The tree is of fine shape, a good grower, and the fruit, though not of the very first class, is very fair and beautiful. A friend of ours says, that it is the most profitable fruit he raises, and all who grow it, speak well of it in this respect. We are glad to see those who live near market towns turning their attention to the best varieties of early apples; it is quite certain that they will find their account in it. The above list comprises the best sorts we know of at present.

Trials of Life in the Country.—A Hint to Visitors from the City.

To the Editor of the American Agriculturist:

I am one of those who have left the city to try farming on a small scale, in the country. My wife is an industrious and frugal housekeeper, and by our combined management, we have paid for our land and have begun to lay up a little against a rainy day. We have built a pleasant cottage, and the trees and flowering plants around it, arranged and set out by our own hands, begin to afford us much satisfaction. Our pears, grapes, apples, and other fruits, are just coming into bearing. Our children helped us plant and cultivate them, and they feel a just pride in the work of their hands. Much as they love to pluck flowers and to eat fruit, they never pick them in wanton wastefulness, but they are in fact as careful of them as are their parents.

But here begins the story of our sorrows. Coming, as we did, from the city, we have frequent visitors from town. They are wont to come in fruit time, and that in flocks. They seem to scent the strawberries and grapes fifty miles off. And when they come, they do not always wait to receive what our limited resources can afford to give, but they help themselves to whatever they can find. Last week, a family, consisting of the mother and six children and a maiden aunt, came, and the way they took to my garden and fruit-orchard was "a caution." While wife and I were busy, they rambled about, as if perfectly at home. My Delaware and Rebecca grape vines were just beginning to favor us with a few clusters. On each, were a few bunches which I had reserved, expecting to exhibit them at the next County Fair. Our visitors picked enough from these to destroy their symmetry and beauty, and of other clusters they ate freely. Then they passed through my young pear trees, tasting right and left, throwing away the half ripe, and devouring or pocketing the others. Most of these trees were now fruiting for the first time, and, after waiting many years for them, I had hoped to enjoy the first taste myself, and to have the pleasure of giving away to appreciating friends what my family did not need. But here they were virtually snatched from my very teeth!

I might go on further with the story of our annoyances and trials, but the foregoing is, perhaps, enough to show you the nature of our troubles. We do not complain so much of the money value of our losses, as of the vexation and disappointment at seeing fruit coolly plucked, after long waiting, and so much labor and care. Some city people—surely not all, or the country would be devastated—but some seem to think that fruit grows spontaneously in the country, and that the supply is unlimited, and

is common property. And the sufferer must not complain to his visitors, lest they call him stingy, but must spread for them a bountiful table, and be good natured and smilingly agreeable. Mr. Editor, you see my sore spot: pardon my wineing, and won't you use your influence through the *Agriculturist*, to cultivate a better public sentiment. A SUFFERER.

["Sufferer" is unfortunate in the character of his visitors, though instances as bad as that he relates do sometimes occur. City people are supposed to be well-bred, and generally are, and we country people all like to have them escape the prison-dwellings of the city, and come and see and enjoy our country homes. Aside from the pleasure their society generally gives, we feel a little self-complacency, in doing a sort of benevolent deed, when we take them through our grounds, and share with them some of the good things from our gardens and fruit yards—though, like "Sufferer," we prefer to have them let us do the gathering, and proffer the fruits. Of course, none but those who need the admonition, will take any offense at the hints of our correspondent.—Ed.]

The Quality of Grapes.

There is perhaps no fruit about which there is such a diversity of opinion and about which tastes differ so much as the grape. Nothing shows more strikingly the difference between a crude and a cultivated taste, than to hear the opinions expressed by the numerous individuals who subject grapes to our inspection. One person will bring us a parcel of grapes which he says are remarkable for their perfume, but before he opens the package we recognize the "perfume" as the foxy odor so disagreeable to an educated palate. We have heard a person declare that he never saw such grapes as grew on his father's farm. "Why a dish of them would fill the whole house with fragrance." This person probably never tasted a good grape, and would be perfectly satisfied with a fruit like the Charter Oak. Those who have based their standard of quality upon this peculiarity of our worst grapes, we have very little hope of. It is a peculiar taste, and argues a defective sense. Others show a more cultivated taste in selecting some of the thin skinned and least musky of the wild grapes, but their knowledge extends only to the fact that there are wild and cultivated grapes, and that the cultivated ones are generally the best. To properly judge of grapes, or any other fruit, it requires not only a refined but a cultivated taste. It needs a naturally delicate palate to distinguish flavors, and this must be educated by experience. A good grape should have a very thin skin, be quite destitute of foxy aroma, and with so delicate a pulp that the seeds can be separated by the tongue; after these prime requisites the qualities of sweetness and flavor are to be considered. We think that the Delaware may be taken as our present standard of a good grape, though with the attention now given to producing new varieties, we look for a fruit which shall be even superior to this variety. We are led to these remarks by receiving several "new seedlings" sent in to us with the regret that they were too early for our great Grape Exhibition. They were sent by persons whose taste for grapes had not been cultivated. Had they been exhibited, the senders would have been disappointed in not getting a prize, and would have been quite surprised to learn that their fruit was condemned as unworthy of cultivation.

My Asparagus Bed.

To the Editor of the American Agriculturist.

My Asparagus bed was set out Oct. 20th, with two-year-old roots, and has pleased me so well that I must tell others how it was done. Perhaps old boots, shoes, leather shavings, bones, horns, stones and other things recommended as needful might have benefitted it, though it apparently lacks for nothing, and a person who cannot get these articles should not be deterred from planting this early and always welcome vegetable. The way I did it was this: On a dry, sandy spot in my garden, I staked off a piece 15x18 feet, manured the surface heavily, and spaded two spits deep, working in another good dressing with the lower spit. The soil was rich to begin with. I set the roots in rows, eighteen inches apart, and nine inches in the row, which gave me 12 rows 15 feet long, each containing 20 roots. The crowns, when covered, were three inches below the surface, and the whole was raked off smooth. Just before Winter set in, I covered the bed with two or three inches of coarse stable manure, the finer portions of which were forked in lightly between the rows in the Spring. Weeds were kept down and the soil frequently stirred. The plants made a fine growth the following season. Since then I have followed the same method as to manuring and keeping the bed clean of weeds, and I have cut more real giant asparagus, each Spring, than could be eaten by a family of eight persons. GARDENER.

Brooklyn, N. Y., Sept. 15th, 1863.

For the American Agriculturist.

Crinoline in the Garden.

I have great regard for the ladies, but must tell them that their broad phylacteries do spoil our gardens. Paths wide enough for their amplitude can not well be afforded. The consequence is that if a delicate plant or trailing vine happens to stand near the margin of a border, it is sure to be crumpled or broken down by their hoops; and if they lean over to admire or pluck a flower, they are very apt to crush down several more. And then, what havoc they make in the green-house—bruising plants and knocking over the pots! How many an amiable gardener scowls when a row of hoops come to his door!

Dear ladies, what shall be done? Can't you take in sails, say about one half? Think about it. Some of our lady friends love to do light work in the garden, morning and evening, but what sad work the dewy plants and the wet ground make with their trailing skirts! "Bloomer" dresses we do not approve of for the parlor, or even the street, or church, but in the garden and kitchen, why may not something of the sort be wisely adopted? The ladies are full of ingenious contrivances, and it would seem that they could devise some sort of compromise between the sweeping folds of the parlor dress and the genuine Bloomer costume. Why should not our fashion-mongers contrive a working dress for ladies, neat, modest, tasteful, and becoming? GARDENER.

APPLES keep best when left upon the trees until quite late in the season. A white frost, and even a slight freezing will not injure them. Pick carefully, and leave them in the orchard or out-house to sweat for a few days, and only take to a cool dry cellar when there is danger of their being injured by hard frost.

SPECIMENS OF GLADIOLUS FROM OUR EXHIBITION TABLES.

Sketched and Engraved for the American Agriculturist.

The Improved French Hybrid Gladiolus.

Some years ago two or more sorts of Sword Lily or Corn-Flag were grown in the gardens, but they did not excite any great admiration. Within a few years the *Gladiolus Gandavensis* and its varieties have been introduced, and have become deservedly popular. Their great beauty, variety of color, and ease of cultivation make them among the most valuable plants for garden decoration. The engraving represents a group of flowers selected from a most magnificent collection exhibited at the *Agriculturist* office by Mr. Andrew Bridgeman, of New-York. The *G. Gandavensis*, is so called because it originated in Gand (Ghent), and it is claimed that it is a hybrid between two old species; however this may be, it sports wonderfully and has produced a great variety of most beautiful sorts,

differing in the size of flower, color and markings. Some are pure white with most delicate purple lines; others unite white, yellow and purple, scarlet or crimson, shaded in the most pleasing manner. The named varieties number several hundreds, and sell at the stores from 20 cts. to \$2 a bulb, according to their rarity. The plants will grow in any good soil; the colors come better if the ground is not made too rich. The bulbs may be planted as soon as the frost is well out of the ground. The best effects are produced by planting strongly contrasted colors in groups of three to five. When a flower stem appears, it needs to be tied to a neat light stake to keep it from being blown over by the winds. When the frost cuts down the foliage, the bulbs are to be taken up and placed in a sheltered place to ripen, and then put up in paper bags until the time for Spring planting.

The bulb planted in the Spring, will usually be found to have multiplied to two or three; and frequently numerous small bulbs, not larger than peas, are found attached. In case of a choice variety, these minute bulbs should be carefully saved and planted, as they will in a couple of years also become good flowering bulbs.

The following is a list of select varieties of *Gladiolus*. It does not by any means comprise all the fine sorts, but these kinds are good and will give satisfaction: Adonis, Archimede, Brencleyensis, Calypso, Comte de Morny, Couranti fulgens, Daphne, Don Juan, Edith, Eugene Verdier, Junon, Louis Van Houtte, Mathilde de Landevoisin, Mazeppa, Napoleon III., Neptune, Osiris, Premices de Mont Rouge, Vesta.

The Rose as a Bedding Plant.

Of upright roses we have often spoken, and shall again speak, for this is their true position. But for variety and novelty, it may frequently be recommended to use them as bedding plants, pegging them to the surface of the ground. To do this well, a bed of deep, rich soil should be prepared. The work should be done with special thoroughness at the outset, because the earth can not be enriched and spaded afterward, as well as with standing roses. Set the plants $1\frac{1}{2}$ to 2 feet apart each way, according to their habit of growth, using only young plants. Peg down the branches to the earth, from the very start, and spread them equally on every side, like verbenas, so as to cover the ground.

Of the kinds most suitable for this treatment, we would name for the latitude of this city and southward: Deconiensis (Tea), Aggripina (China), Mrs. Bosanquet and Malmaison (Bourbons); for northward of this, we would propose: Hermosa (Bourbon), Giant of Battles, Mad. Laffay, and Duc d'Aumale (hybrid perpetuals). Cover these beds with coarse litter in the Fall, uncover by middle of April, and prune out the oldest wood and peg all down in good order. The effect of such a bed is very pleasing.

About Crosses and Hybrids.

W. K. R., of Hastings, N. Y., asks us to discuss this subject in the *Agriculturist*. We can only briefly answer some of his questions without going at length into a matter which is involved in much obscurity, and one which treated at any length would concern but a small minority of our readers. Those interested in the subject will find some very pleasant reading in the 8th chapter of Darwin on the Origin of Species. The term *hybrid* is used very loosely by gardeners and florists. By the best authors it is applied only to the product of one species fertilized by another distinct species. Hybrids are rarely fertile, though they may be fertilized by the pollen of one of the parents, and then the progeny tends to revert to the original character of the parents. Hybrids take place in nature, though rarely, and are produced to some extent by the care of the cultivator. The product of the union of two varieties of the same species is properly called a *cross*, or cross breed; it takes place with the greatest facility, and requires much care to prevent the loss in this way of desirable sorts of cultivated plants. We know of no instance where the crossing extends from genus to genus. We shall look with much interest for the result of Mr. R's. experiment in impregnating the Tomato with the pollen of the Red Pepper. Should a hybrid be obtained, it will go to show that the Tomato was improp-

erly separated from the genus *Solanum*. We know of no instance in which the character of the immediate fruit is affected by a cross fertilization, the influence being confined to the seed, and showing its effects in the next generation, from the seed. We do not assert that this is a settled point; we have had statements to the contrary, but have seen no proof. It is an interesting subject for experiment and observation.

THE HOUSEHOLD.

"Bitters"—Worse than a Humbug.

The land is full of bitterness. We speak not now of the woe and anguish caused by war, but of what promises to be scarcely less disastrous in its results upon individuals and families. During the present year we have traveled four or five thousand miles, through different parts of the country. In all that route there has hardly been a point where the eye did not meet an advertisement of somebody's "Bitters." Upon every available space, on the walls of buildings, on the fences, on the surface of rocks and stones, upon the bridges and telegraph poles, indeed every where "Bitters,"—"Strengthening Bitters,"—"Healing Bitters,"—"Invigorating Bitters,"—"Life Saving Bitters," or some other "Bitters"—stare one in the face. This is most strikingly the case in some portions of Illinois. So, too, the newspapers abound in advertisements of these various bitters; and in every hotel, tavern, and down to the smallest 3 by 4 drinking shop, attractive rows of bottles labeled "Bitters" are every where to be seen. We know of large glass manufacturing run almost exclusively in the manufacture of bottles for Bitters.—Now all this costs a "mint of money," and this money has already come and is coming from those who buy and drink those Bitters—showing an immense consumption.

But what are these "Bitters"?—With scarcely an exception, they are essentially a cheap form of alcohol—whiskey, gin, or rum. Most contain a little bitter extract—some more, some less—added as a blind, or as a slight tonic. Take out the alcohol, and all that remains would not amount to much—good or bad. Whiskey, or gin, that under its own proper name would not sell for fifty cents a gallon, is put into bottles costing 4 to 7 cents each, five to eight bottles to the gallon, labeled at the cost of a penny, and sold at a dollar a bottle, or at least five dollars a gallon. The attractive label, the great stories told of the healing and strengthening properties, lead people to pay these prices. This much is sheer humbug.—But there is a worse feature. We stopped at the house of a western farmer who would not for the world incite in his children a taste for and love of alcoholic drinks. Yet influenced by the advertisement in his family paper, and a religious one at that, he had bought and used several bottles of these bitters, and supposing us to be wearied with a long day's travel, he proffered us a glass of "strengthening bitters." Two of his little boys were given a spoonful each before breakfast—"to keep off the chills." We told him he was feeding them with gin, and laying the foundation for a drunkard's life and a drunkard's grave.

We constantly meet with persons who daily use these "bitters." The temporary stimulant afforded by the alcohol, deceives them into the belief that they are "invigorating," or "strengthening." When the excitement subsides, and the natural reaction and lassitude follow, they take another dose, and so go on. We say in all seriousness, that the enormous sale and use of these "bitters" is doing more to produce wide-spread dissipation and drunkenness, by begetting a taste for alcohol, than can be counteracted by the efforts of all the Temperance Societies that have yet been organized. Let us beg of every man who would not bring up his family to be drunkards, and who would keep out of temptation himself, to banish these "bitters" of every kind from his house, and discourage their sale in the community. We have had column after column

of advertisements of them offered for the *Agriculturist*, but we would as soon admit advertisements of sugar pellets which we knew to contain concealed arsenic or strychnine.

A Lung Protector.

A very absurd fashion requires men, while wearing four to eight thicknesses of cloth around most of the upper part of the body, to leave an open place in front of the lungs for the display of their white linen bosoms, and gold studs—if they have them. This front of the neck and upper chest is the very part that should be most carefully guarded from changes of temperature, for the lungs lie just back of and under the collar bone. As we can not compel the correction of the fashions, by anything we may say in the unfashionable *American Agriculturist*, let us give our antidote, one which has to our certain knowledge proved efficacious in several instances.—There is a species of soft leather, sometimes real "Chamois" skin, but usually a sheep-skin imitation, which is sold almost every where for 25 to 50 cents per skin. The imitation answers as well as the real Chamois (pronounced shammy).

FORM OF THE PROTECTOR.

From the smaller end of the skin, cut off a piece like the engraving above. The rest of the skin may be used for cleaning carriages, windows, silver, etc. Put strings on each corner, to fasten it around the neck and waist. This kind of leather is so open that one can blow a light out through it, and on this account it is valuable to shut out cold, and at the same time not retain perspiration. It can be washed when soiled, the same as flannel, except that the suds and rinsing water should not be quite so hot as for flannel.

For a Sore Throat.

The best remedy we have found for a sore throat, is, on retiring to rest, to rub on the outside a little "Volatile Liniment," and swallow slowly a few drops of paregoric, letting it dissolve in the saliva, and spread along down the inflamed parts. The liniment is generally sufficient alone. Volatile Liniment is simply a mixture of sweet oil and aqua ammonia (called liquid hartshorn). These are put in a vial and shaken, using such proportion as to form a semi-liquid soap. An ounce or two can be got cheaply at the druggist's, and if tightly corked, it will keep for months. Rub it on with the fingers. We find nothing better than this for soreness of the chest or joints, or for lameness, stiff neck, etc.

To Stop Coughing.

Slight irritation of the throat may be relieved by sipping a little thick slippery elm tea, or by sucking a piece of gum arabic. These articles coat over the mucous membrane, and prevent the irritation of the air. A very few drops of paregoric held in the mouth, and allowed to trickle down the throat, will allay coughing. The best cough medicine for children, one which we have used for several years with entire satisfaction is the following:

Mix in a vial equal parts of *paregoric*, *castor oil*, and *syrup of ipecac*. Always shake well just before using. A few drops of this swallowed, but not washed down by water or other fluid, will almost always soothe a cough. Repeat the dose as often as the coughing returns. From one-fourth to one-half a teaspoonful, or even a whole teaspoonful may be given when a lesser quantity does not suffice. A large dose after a full meal may produce a little nausea. Children subject to coughs should eat very light suppers, and indeed all children should eat much less, and simpler food, at night than at morning or noon. The above mixture may be kept on hand ready prepared, as it does not deteriorate if kept corked. It may interest those afraid of mineral medicines (though they partake freely of common salt which is a mineral) to know that the ingredients are all "vegetable."

Soda and Mineral Waters.

If properly prepared, "soda water" is a refreshing and harmless drink. Though it contains no soda, it is called "soda water" because soda was formerly used in its preparation; as made at present, it is simply a solution of carbonic acid in water. Carbonic acid is a gas which is very soluble in water: it is the ingredient which gives the effervescence or sparkling quality to bottled cider, ale, beer, etc., and is very strikingly perceptible when a little saleratus or cooking soda is dropped into vinegar. It is seen bubbling up from the liquid, and making it to froth and foam. Under ordinary circumstances, water absorbs its own bulk of this gas; it is present, to a greater or less extent, in all drinking water, and it is its absence which gives water that has been boiled so flat a taste. Under pressure, water will absorb a much larger quantity of carbonic acid, and by means of a force-pump, the gas may be forced into water in a strong closed vessel, and it is thus made to dissolve many times its own bulk of the gas. This is the way in which soda water is made. The fountain, a strong vessel of iron or of copper lined with tin, contains pure water, and the gas is driven in by means of a force-pump, until 15 or more times its bulk of gas has been absorbed by the water. When an outlet is afforded by opening the stop-cock of the fountain, the elastic gas forces the water out, and its escape, from its solution in water under pressure, causes the foaming which we see in a glass of soda water. When taken into the stomach, carbonic acid is not only a pleasant tonic, in health, but very useful in some forms of disease, and we often have prescribed in fevers, soda powders, which are made of carbonate of soda and tartaric acid, and produce soda water in an extemporaneous way.

"Mineral waters" are those natural waters which contain so much mineral matter in solution as to affect the taste, and impart a medicinal quality.

PORTABLE GLASS SODA FOUNTAIN.

These waters hold in solution various salts, iron, sulphur, etc., and various springs of water of this character have a high reputation. In our own country, the Saratoga and several other noted springs are places of great resort for invalids; and in Europe there are certain springs of even greater reputation. It is probable that the good effects of these waters are in great measure counteracted by the miserable hotel life which is followed at such places. All the celebrated waters have been accurately analyzed, and chemical skill has succeeded in making them artificially, and in reproducing exactly similar water to that furnished by the celebrated medicinal springs. Now, one can drink

the waters without the annoyance of travel or the discomfort of a watering-place hotel, but surrounded by the conveniences of his own home. One of the most successful manufacturers of such artificial waters is Mr. Carl Shultz, of the firm of Shultz & Warker, of this City. Mr. Shultz has brought his well-known chemical knowledge to the production of an article of general utility. The waters are put up in strong glass fountains, the soda fountain in miniature, and the plain carbonic acid (or soda) water, or the various mineral waters, can be drawn in the room of the patient, in all perfection and purity. As usually drawn from tinned copper fountains, there is a danger of metallic impregnation, as the tin used for this purpose is most generally adulterated with lead. In the apparatus used by Messrs. S. & W., there is no possibility that such an impurity can occur. The water is liberated from the fountain by touching a spring with the finger, and may be drawn in any quantity desired. We present an engraving of one of these fountains, which are really neat, convenient affairs. They are sent around to families ready filled, and the bottles are called for when empty, or exchanged for others. The low price (10 to 15 cents per quart fountain,) at which soda and several kinds of mineral waters are delivered, is an important consideration, and they are worthy the attention of physicians and others having occasion to use them.

For the American Agriculturist.
Water, Hard and Soft.

The medicinal effects of water are not enough considered. Every one knows that there is some friction in the kitchen when hard water has to be employed for washing, but there is as much friction in the human frame when it is used constantly for drinking. Medical men, from Hippocrates to this day, testify that the habitual use of hard water tends to constipate the bowels. The water for domestic use in Liverpool, is quite hard, and a large proportion of the inhabitants suffer from visceral obstructions, a malady which generally abates when the sufferers leave the city and go where soft water is at command. In the best hydropathic establishments of Europe and this country, the aim of the physicians is, to get the "softest and purest water." At the famous Malvern institution, where thousands of invalids resort annually to drink the healing springs, "the spring water in the highest repute for medicinal quality, is a water only remarkable for its purity."

Who does not know that horses have an instinctive love of soft water, and refuse that from wells, if they can have access to running streams. It is the tendency of such water to produce a rough coat on horses, as well as to disturb their digestion. In England, where great pains are taken with race horses, soft water is often carried for miles to the race-course, lest the horses should suffer from hard water furnished on the ground. Youatt says: "Instinct or experience has made the horse conscious of this (the difference in water,) for he will never drink hard water if he has access to soft; he will leave the most transparent water of the well for a river, although the water may be turbid, and even for the muddiest pool." The same thing is true, more or less, with sheep and other stock.

From this, it is plainly of much importance to provide wholesome water for our families and for our domestic animals. For home use, where children and others suffer from the water in common use, a filtering cistern, or one of the various filters in market becomes an indispensable article. M.

[Pure water is desirable, but spring water may be as impure as that from wells. All water passing through the soil, dissolves out soluble minerals or salts. For this reason the water of running streams is mineralized. The ordinary filter will not remove these dissolved substances: it merely takes out the coarser materials. Rain-water is the only pure liquid to be depended upon. If caught from high, clean roofs, and kept in clean cisterns, filtering is unnecessary. The peculiar taste is owing to the absence of flavoring earthy salts. After

a little practice, rain water is relished better than any well or spring water. We have not used anything but cloud-distilled water for years, and now well water has a disagreeable mineral taste.—Ed.]

Water-Proof Walks.

A method of making hard dry walks is coming into use in some parts of England, which in certain circumstances must be excellent. A hard dry bottom being prepared, it is coated with about two inches of hydraulic mortar, made by mixing together about six measures of clean gravel, three measures of sharp sand, and one measure of good hydraulic lime—usually called water-lime. The best hydraulic lime in England is called Portland Cement. Probably a larger proportion of our common hydraulic lime would be required. Those who have not access to sea-shore gravel, can usually get that which will answer, by sifting over any soil which contains pebbles and gravel. This will be improved by washing it, which can be readily done by putting a bushel or so in a barrel, and fill with water, stir it well, and pour off the water rapidly. The washing may be repeated two or three times if necessary. As the mixture sets quickly, only a few bushels should be wet at a time, and this be applied at once and smoothed down. The surface should be raised in the middle, and slope gently and evenly to the sides. The mortar can be applied and smoothed with a common shovel. It will thus form a hard surface from which water will flow off. Unless the walk bed be hard, or thoroughly under-drained, so as to be dry to the depth of 12 or 15 inches, it will heave and crack by freezing in winter. A walk like the above will not be expensive, and if well made will last a century, and not be troubled with weeds or worms. The same bedding answers admirably for the floors of cellars, green-houses, poultry houses, etc.

"Cheap Thread—One Cent a Spool!"

On our way home from the *Agriculturist* Office last night, we saw a poor laboring woman exhibiting to her friend a lot of spool thread, which she had "bought very cheap" of a "street merchant"—only one cent a spool." This morning we visited several of the "street merchants" who have displayed upon the sidewalks, and at the street corners, large heaps, a bushel or more each, of this cheap thread, and we bought a few samples to examine. Though appearing to be full spools of good thread, on measuring the length, the average amount on a spool is only $11\frac{1}{4}$ yards! At this rate "200" yards would cost about 18 cents. The best spool cotton thread is retailed now at 8 to 10 cents, the spools warranted to contain, and they generally do contain, 200 yards. But the worst thing about this "cheap thread" is, that it has no strength. The poor women will find, after spending hours and days in using it, that the stitches will break very readily, and before an ordinary garment is worn out, almost as much good thread will be needed for mending, as would have sufficed to make up the garment at first. The truth is, poor thread is very dear, even if it be given to a person. The very best is cheapest, at any price. We allude to this matter now, because that, owing to the present higher price of thread, hundreds of thousands of spools of poor stuff are being worked into the market—often mixed with better sorts.

Sealing Fruit-Bottles.

Mrs. C. H. M. Newell, Hampden Co., Mass., writes to the *Agriculturist*: "Among your many plans for securing jars of fruit, I find no mention of one that I have used several years, and find it preferable to any kind of patent fastening, and even better than the patty-pan arrangement. Cut circular pieces of thick, stout cloth, sufficiently large to tie over the jar or can. On these, cover with cement a space that will fit the opening, and

extend over the rim. While filling the jars, lay the cemented covers on the bottom of the stove oven, to soften. When the jar is ready, wipe the rim dry, and apply the covers, cement side down, smoothing out the wrinkles and tying it with a strong string. Afterward cover the top with some of the cement thinly spread. A few minutes will show, by the depression of the cover, that the contents are secure. I think you will find it the cheapest, easiest, and most expeditious manner of sealing that has come to your notice. Very many use it, and all give it their unqualified approval. The cement I use is made with 1 oz. rosin, 1 oz. gum shellac, 1 cubic inch of bees wax: melt these in a tin cup, and mix thoroughly; use gentle heat to melt or remelt, as great heat may granulate the shellac."

Don't Rock the Baby.

If all the ultimate consequences of one's acts are to be laid to his charge, the man who invented rocking cradles for children, rests under a fearful load of responsibility. The down-right murder of tens of thousands of infants, and the weakened brains of hundreds of thousands of adults, are undoubted results of his invention. To rock a child in a cradle, or to swing him in a crib, amounts to just this: *the rapid motion disturbs the natural flow of the blood, and produces stupor or drowsiness.* Can any body suppose for a moment that such an operation is a healthful one? Every one knows the dizzy and often sickening effect of moving rapidly in a swing; yet wherein does this differ from the motion a child receives when rocked in a cradle? It is equivalent to lying in a ship berth during a violent storm, and that sickens nine people out of ten. A very gentle, slow motion may sometimes be soothing, though always of doubtful expediency, but to move a cradle as rapidly as the swing of a pendulum three feet long, that is once in a second, is positive cruelty. We always feel like grasping and staying the arm of the mother or nurse who, to secure quietude, swings the cradle or crib with a rapidity equal to that of a pendulum a foot long. If any mother is disposed to laugh at our suggestions or consider them whimsical, we beg of her to have a bed or cot hung on cords, then lie down in it herself, and have some one swing it with the same rapidity that she allows the cradle to be rocked. What she will experience in both head and stomach, is just what the infant experiences.—

We insist that this rocking of children is a useless habit. If not accustomed to rocking, they will go to sleep quite as well when lying quietly, as when shaken in a cradle. If they do not, there is trouble from sickness, or hunger, or more likely from an over-loaded stomach; and though the rocking may produce a temporary stupor, the trouble is made worse thereafter, by the unnatural means taken to produce quiet for the time being.

Curing Pork Without Brine.

A subscriber, W. C., of Carbon Co., Pa., sends to his co-readers of the *American Agriculturist* his method of curing pork, which he has tried for several years with good results, and the plan is now adopted by his neighbors, all deeming it superior in several respects to the brine method: "For each hundred pounds of meat, take 5 lbs. of salt, 1 lb. of sugar, and $\frac{1}{2}$ ounce of saltpeter. Mix the ingredients well, then thoroughly rub both the flesh and the skin sides of the pork. I always do the rubbing in with the hand, although it might be well to use something else in cold weather. The meat should be slightly cut from the bones and filled with the mixture. After this operation is completed, the pork must be layed out on boards for three weeks, dropping on the pieces what of the mixture may remain. At the expiration of three weeks it is fit for the smoke-house."

ZINC VESSELS POISONOUS.—"S. M.," asks why no notice of zinc milk pans has appeared in the *American Agriculturist*. She thinks "they are

light, convenient, cheaper than tin, and if not punched through by sharp points, they are almost everlasting."—*Answer*:—Zinc is very easily acted upon chemically (that is, corroded or rusted,) and the salts formed are poisonous; a very small quantity produces vomiting. As these salts are of light color and easily dissolved, they are not readily seen. Sour milk, fruits, etc., constantly eat off and dissolve portions of the zinc. No substances used for human or animal food should be placed in zinc vessels, or those lined with zinc.

Pickle the Small Onions for Soldiers.

From a letter to the *American Agriculturist*, written by a nurse at one of the soldiers' hospitals at the South, and from a variety of sources, we learn that our soldiers, both in hospitals and in the field, have a strong liking for pickled onions. Almost every one cultivating a garden has more or less of small onions, too small to boil well, but just the thing for pickling, and we urge them to save every one, and pickle them to be sent in bottles, jars, or wide mouthed jugs, to the Sanitary or Christian Commissions, or directly to some hospital or camp. At our request a good housekeeper communicates her method for the readers of the *Agriculturist* as follows: Peel the onions; lay them in weak brine over night; scald them in fresh water for five minutes, not to soften them; drain off all the water; pour over them hot vinegar previously seasoned with a little cloves, mustard, and pepper boiled in. The stronger the vinegar, the less spices required to keep them. After standing two or three days, pour off the vinegar, scald, and return it to the onions. They may then be kept in any convenient covered vessel.

Drying Green Corn—Good Method.

"Housekeeper," sends to the *American Agriculturist* her method of preserving green sweet corn, which she says is always successful. (We have for a long time satisfactorily practised a similar method both with sweet corn and the common sorts): "Gather the corn while still soft; simply scald it on the ears, not boiling it soft; cut it off with a knife; spread it on plates, and dry quickly in the sun when hot, and by the fire or in an oven, at night, and when the sun is not shining warm. It dries quickly, and therefore needs rapid drying, but too high heat spoils it. Keep in a bag in a dry place. The secret of having it good when cooked, is to soak it over night, and boil it well in the same water. It is then almost as good, at any time of the year, as when first gathered. Add no more water in boiling, than will cook away, but avoid the least scorching. Any common corn may be treated in the same way, but is improved by adding a little sugar when cooking. Season with salt, and milk and butter boiled in, the same as for green peas or beans. Cream is still better."

"Higdum."

A lady sends to the *Agriculturist* a recipe for a pickle under the above name, which she says is much liked by her friends. We published something similar, a few years since, but can not recommend the compound as a particularly attractive or digestible one. It may be pleasing to some, and healthful to those who have good teeth to thoroughly masticate the stuff before swallowing it—if they will use the said teeth: "Take equal amounts of onions, green tomatoes, and of ripe cucumbers from which the seeds and skins are removed. Chop the whole together very fine; sprinkle salt over the mass, let it stand over night, and drain off the fluid thoroughly through a sieve or colander; pour over the mass and mix well with it hot vinegar, previously boiled with plenty of mustard, cloves, black pepper, and red (Cayenne) pepper. After a few days drain off the vinegar, scald, and return it. Those who relish sweet oil in salads, add this, after the final scalding. Some add wine at the same time."

[We should think there is quite enough in a mixture like the above, without adding the wine.—*Ed.*]

Pickled Green Corn.—A lady correspondent of the *American Agriculturist* says she has tried various methods for preserving green corn, but has always failed to keep it in cans, or in any other way than by drying or pickling it. She finds that by pickling it in strong vinegar it makes a very good winter and spring relish.—Another correspondent directs as follows: To one gallon of corn cut from the cob, add one pint of salt. This can be freshened out by putting it into clear water, letting it stand about one hour, changing the water three or four times. Cooked in milk, with butter and pepper added to suit the taste, it forms a palatable dish for winter.

Apple Butter.—"Mary" of Alliance, O., communicates to the *Agriculturist* the following directions for making apple butter: Boil a barrel of cider from sweet apples, to one third its original bulk, after having first taken out two pailfuls in which to cook the apples. Nicely pare and core sweet apples enough to make two bushels of fruit when finished. Boil these in the cider which was reserved for the purpose, until they are a little soft, then pour the whole into the boiled cider, while hot, and cook; stir it until a pulp. Sauce thus prepared, will keep good for several years.

Bird's Nest Sage Pudding.—Contributed to the *American Agriculturist*, by Mrs. P. J. S., of Litchfield Co., Conn.: Pare and cover enough apples to cover the bottom of your pudding dish. Soak one cup of sage in as much water as it will absorb, and pour it over the apples; bake until the apples are cooked soft. If it dries much in cooking, add water. The dish can be covered to prevent a hard crust forming. Other fruits can be used instead of apples. Eat with cream, milk and sugar, or other sauce made according to the taste.

BOYS & GIRLS' COLUMNS.

A Ghost Story.

Do any of our young readers ever get frightened when sleeping alone in a room, or when going through a wood, or a secluded road, or by a grave yard, by imagining that they do see or may see a ghost? Doubtless many of them have had such experiences. The writer had, when a boy, and he has never conversed on the subject, with a person who had not thus suffered. But he has grown older and wiser now, and after studying the subject, is so thoroughly convinced that there has never been a real ghost and never will be, that he could sleep as quietly near a cemetery or in a cave, as if no hobgoblin stories had ever been whispered into childish ears.—We have just read a long ghost story of which the following is the substance. A man had been fishing all day, and retired to rest at night at the house of a friend. He was awakened after midnight by a tapping at his window, and saw some white object moving about his room. He also plainly heard a curious sound "fit," "fit," "fit." In his fright, he called for his host, who ran in with a light, but was tripped up, and his light put out in the fall. Both sprang from the room, being tripped several times before reaching the door, and they waited for daylight in great terror. Then the mystery was thus explained. The fisherman on going to his room had unjointed his rod and carried it with him, forgetting to remove the minnow (little fish) used as a bait. A large white cat coming in, had snapped at the bait and been caught by the hook. She drew the line from the reel and wound it around the bed posts and chairs, and in striving to get loose made the noise "fit," "fit," "fit." The frightened man had heard these sounds and the beating of a lilac bush against the window, had seen the white ghost (cat), and stumbled over the line. Every ghost that has been reported, if investigated at the time, would prove to be as unreal, or real, as the white cat caught on a fish-hook.

Intelligence of Fishes.

A writer in a recent English work, "The Angler Naturalist," says: "That fish are not so stupid as many people suppose, is proved by a little incident which was observed at the Zoological Gardens. In some plate-glass tanks were a pike and several perch. These fishes took no notice of our entrance, and continued perfectly supine, though the keeper walked several times past their

tanks, as if about to feed them; but when he walked away from them toward the cupboard where the net with which the baits were caught, was kept, the stolid demeanor of the fish, both pike and perch, gave way to the most intense excitement. They rushed to and fro across their enclosures, straining their noses against the glass, erecting their fins, and exhibiting every token of agitation; and when the keeper, having taken the net, proceeded with it toward the bait tank, the whole shoal fastened their eyes upon him, following every movement, and constantly veering round, as if under magnetic attraction, toward whichever part of the room he turned. It was evident that these fish knew where the net was kept, that the keeper was going to fetch it, and that his doing so was a preliminary to their being fed."

Not Quite a Meteor.

A correspondent of the *Agriculturist* communicates the following incident, which recently occurred near Chillicothe, O.—Some boys who were playing in a cornfield, were startled by a loud rumbling noise not far from them, and on searching for the cause, soon discovered a large boulder (rock), which had evidently just arrived from parts unknown. One of them applied his bare foot to it, when to his great astonishment he found it extremely hot, as though it had just been ejected from the crater of some volcano. Then there was, of course, great wonder where the strange rock could have come from; some thought it had fallen from the sky, as they had read accounts of such phenomena; others supposed a volcano might indeed have burst out at no great distance. If the investigation had stopped with mere guessing, as has often happened when strange occurrences have been observed, the stone would have made quite a noise in the community; but some persevering youngster continued his efforts to solve the mystery, and was at last rewarded with the true explanation. Some one had been burning brush on a steep hill not far distant, and the boulder being set free by the fire consuming the sticks which held it in place, had come tumbling down to the plain below, and thus the meteoric explanation and other startling theories were quickly exploded.

New Puzzles to be Answered.

No. 53. *Mathematical Problem.*—Contributed to the *American Agriculturist* by John White, Alleghany Co., Pa. A farmer bought a circular tract of land at the rate of \$1 a foot for the diameter. He surrounded it with a post and rail fence at \$2 a panel, each panel being 12 feet long, and stocked it with sheep at \$2 per head. His sheep cost him three times as much as his fence, and he had 50 feet square of pasture for every sheep. What did the land, fence, and sheep, each cost?

No. 54. *Illustrated Rebus.*—A truth worth considering.

Answers to Problems and Puzzles.

Answers to Problems in September *Agriculturist* page 281. *Illustrated Rebus*, (No. 50).—C on tin ewc din dust rib rings C on tent men tea; which, properly arranged and read by the sound, reads: Continued industry brings contentment. No. 51. *Arithmetical Problem.*—A little study of this example shows that the key to its solution is found in the mathematical truth that "The product of the sum and difference of two numbers is equal to the difference of their squares." We leave it unanswered for another month, that our young readers may attempt to successfully use this key. Several have already done so. No. 52. *Enigma.*—The mystical word is Hannah. No. 49. *Mathematical Problem.*—(August No., page 249.) A could do it in 6 days; B, in 3 days.

The following have sent in correct answers; the numbers indicate the problems, etc., answered by each: Henry H. Osgood, 46; (we like to receive new problems, accompanied with solutions;) Orient, 44; M. E. Brotherton, 44; George Eleock, 46; S. A. Dickey, 41; W. W. Dickey, 41; "Little Falls," 46; J. N. Miller, 44; C. A. Kaufman, 44; L. O. Gay, 46; Charles T. Pettit, 48; Aaron S. Littleton, 48; James D. McGiffert, 49, 50, 51; W. Jones Rodgers, 51; Wat Van Fleet, 51; Charles P. Hoffman, 51; W. Marsh, 49; John White, 49, 50, 51, 52; D. G. Jones, 49; A. A. Rudolph, 52; C. B. Miller, 49, 50,

CHILDREN OPENING THE GATE.—TRUE POLITENESS.

Engraved for the American Agriculturist.

What is the first thought on looking at this beautiful engraving? Is it about the ragged clothing of the largest boy? No, certainly; for his open, pleasant countenance, and his respectful salute, made by carrying his hand to the place where a hat ought to be, at once make you feel "I like that boy."—Not a thought is given to what he wears. His homely garb makes his kindly look and polite manner even more noticeable. *Good manners are better than fine clothing.* That is the first lesson of the picture.—But there is something more to be noticed. See how trustingly the lad's little sister nestles up to his side, and you can also tell by his brother's face that they are on the best of terms. This lad's politeness, then, is something more than *appearing* pleasant; it springs from a loving nature. He has taken no lessons in the parlor, but his heart prompts him to kind feelings, which show themselves in looks and actions: that is true politeness. We have seen a young man full of smiles and bows for young ladies, when in company, but rude and selfish toward his sister at home; and there are young ladies, so called, that are all sweetness in the parlor, but unfeeling in their treatment of their mothers; such might learn a good lesson from this poor country lad. Many persons who are good at heart might be greatly improved by taking more pains to be agreeable, but it is better to be good and kind, without appearing so, than to *appear* so without possessing those traits. Politeness may be called the oil of society, which enables persons to easily pass along without unpleasant friction. It has made more than one man's fortune. An instance is related of a former Governor of one of the Western States. When a boy, he was once holding a calf, while his mother was milking

the cow. A gentleman approached and said, "Why don't you take off your hat, my little man?" "So I will, sir, if you will hold the calf," replied the boy, respectfully. The gentleman was pleased with the quick answer, but still more with the pleasant way in which it was spoken. He at once became the boy's friend, helped him to an education, and the boy rose to distinction.—But what are these children looking at? Something in the picture tells you, and it will be pleasant to study it out. We think they have opened the gate for a man on horseback.

Boys' and Girls' Garden—No. 7.

The season of flowers has nearly past, and if you have carefully read and thought about what has been said concerning them, you will no doubt wish that it might have been longer, to study new specimens. But we have not yet done with the plants chosen for illustration. After the flower comes the *fruit*, and there is something to be learned about this. In general we are accustomed to regard fruit as something eatable, but correctly speaking, it is the ripened *pistils* of the flower, no matter what its character. In other lessons we have tried to show you the relation of the different parts of the flower, and you have probably observed that they were all subservient to the pistils: the floral envelopes—the calyx and corolla—though they make up the showy part of the flower, are only intended to surround and protect the more important parts. The stamens fulfill their office in furnishing pollen to fertilize the ovules contained in the pistil, in order that they may become seeds. The whole life of the plant is directed towards the formation of seeds by which

to continue its kind, and as the seeds are contained in the ripened pistil, it will be seen that it is the most important part of the flower. After the ovules are fertilized, the petals, stamens, and sometimes the calyx, fall away, and the pistil continues to grow, to accommodate the rapidly-increasing seeds. When the pistil and the enclosed seeds are ripe, they together form the fruit. The fruit presents a great many different forms, and the pistils frequently become very much changed from what we have known them in the flower. It was stated in the last lesson that the Pea had one of the simplest forms of pistil. Garden peas are generally gone by this time, but you will find some pods still on the Sweet Pea. The pea-pod is the fruit of the pea: that is, it is the matured pistil. The change which has taken place is mainly one of size. The little flat green pistil has very much enlarged, and the minute ovules it contained, which were smaller than a pin's head, have become full-sized peas. You will recollect it was stated that all the parts of the flower were to be looked upon as leaves modified to serve a particular purpose, and you had no difficulty in understanding that this might be the case with parts of the calyx and corolla: with the other parts of the flower it is perhaps more difficult to make you see this. Still the botanist looks upon the pistil as a modified leaf, or leaves, and he thinks that you can have no difficulty in imagining a pea-pod as a leaf folded together and bearing the peas on the part where the edges of the leaves meet. Imagine the edges of the leaves turned in a little, and you will see that they form a place to which the ovules are attached. This portion is called the *placenta*, and is a mere line in the pea, but it is much more conspicuous in other fruits.

The pistil of the pea, in ripening to become the fruit, undergoes but little change except that of size. The style withers away and the ovary grows on to form the fruit, which in this case is a pod. The ovary when ripe is called the *pericarp* (meaning around the fruit,) and this in the pea remains thin and leaf-like. The fruit of the

Fig. 34.—HALF OF A PEA POD.

Morning Glory is unlike that of the pea in several respects. The pistil of the Morning Glory is a compound one and we have a compound fruit. If we cut across the fruit before it is quite ripe we find that there are three divisions separating it into three compartments or *cells*, and each of the cells contains two large seeds.—When the fruit is quite ripe the pericarp becomes dry and paper like and comes apart in three pieces to allow the seeds to fall out. The fruit of the Tomato looks very unlike that of the Morning Glory, but upon cutting it open we shall find that it is not so very different. For this examination it is necessary to select a roundish and rather small Tomato, as by high cultivation the fruit has become monstrous and very much changed from its natural condition, which is to have two or three cells. The round, smooth, and regularly shaped Tomato will, when cut open crosswise, generally present the appearance represented in the figure given below. You will notice that in ripening the pericarp has become very much changed, instead of being dry and thin, as in the Pea and Morning Glory, it has become thick and pulpy. You will generally find three divisions showing that the ovary was three celled. The placenta is very large—the white portion in the engraving—and bears a great number of seeds distributed all over its surface. Each seed is

Fig. 35.—MORNING GLORY FRUIT.

surrounded by an abundant pulp. Pulpy fruits like the Tomato are called berries. The Melon when cut open shows you three placentas to which the seeds are attached, but they are not united in the centre, as in the Tomato.

Fig. 36.—TOMATO CUT OPEN.

Origin of the Name, "Canada."

Origin of the Name, "Canada."

A book printed in London, in 1698, written by L. Hennepin, and entitled, "A New Discovery of a Country Greater than Europe," gives the following explanation of the name "Canada." "The Spaniards were the first who discovered this country; but at their arrival, having found nothing considerable in it, they abandoned it, and called it 'Il Capa di Nada,' that is, a Cape of nothing; hence by corruption sprung the word Canada, which we use in all our maps." More recent explorers and settlers have discovered that the name was very far from expressing the truth.

Indian Fun—A Snake Story.

The following occurrence was related by Col. Edward Raymond, one of the earliest settlers near Lake Champlain, N. Y. He was on the lake in a canoe with an Indian named Big Bear, whom he had employed to row him to a distant point. In their course they passed near a sloping ledge of rocks where lay a large number of rattlesnakes asleep in the sun. The Indian looked at the Col., and inquired, "Raymun love fun?" "Yes," was the reply. "Well, then, Raymun have fun; mind Indian and hole a glum" (keep still). So he rowed silently to the shore, cut a crocheted stick of hazel, and carefully placed the crocheted stick on the neck of a serpent that lay asleep close by the water's edge. "Take um now Raymun; hole fass." The Col. then took hold of the stick, keeping the serpent down, while Big Bear tied up a little sack of powder with a slow match attached to it. He

made this fast to the snake's tail, lighted the match, and gave the order "Let um go," at the same time pushing the canoe away from the shore. The snake being liberated, crawled away to his den. Big Bear immediately stood up and clapped his hands, making as loud a noise as possible, which roused the snakes, and they, too, quickly disappeared. "Now look Raymun, now look, see fun," said he, and in about a minute the powder exploded, when there was fun alive, for the men, though not for the reptiles. The snakes in hundreds covered the rocks, all hissing, rattling, twining, twirling, and jumping, in every way imaginable. Col. Raymond burst into a loud laugh, but the Indian, true to his nature, maintained the utmost gravity, though doubtless he inwardly enjoyed the sport quite as well as his friend.

Curious Letter.

An old German work contains the following curious letter from the manager of a travelling theatrical company, to his business agent: "We have arrived here safe, after a long and troublesome journey, the ordered goods have arrived in good order. The messenger has brought us, *snow and hail*, in good order, the *storm* came one day later. I am sorry to say that the *thunder* burst up and the *lightning* we had to patch up also. The *ocean* and *rivers*, I wish you to send by canal as the freight is cheaper, and do not forget to send us new *clouds*, and a new *sun*. But the most important thing we want is a *Bay*, as ours has been burnt. Then we want a few yards of *forests*, and at least twenty yards of clear *air*. Roll them all up, and send them immediately." These terms referred to the different parts of the scenery on the stage.

A Modest Request—A Capital Story.

It is related of President Lincoln, that recently a farmer applied to him to secure his assistance in collecting a bill against the government, for damages done by troops passing through his premises. The President referred him to the proper officer, whose duty it was to attend to such matters. But the man was anxious that Mr. Lincoln should examine the case personally, and give an order to have it settled. "Then," said he, "they will attend to it at once; otherwise I may have to wait a long time." "But I have no leisure to look after such things," said the President. "It won't take but a few minutes," urged the man. "You remind me of what occurred to a friend of mine on the Mississippi river," said the President. "He was Captain of a steamboat, and when passing through the rapids, he always took the wheel, and steered the boat himself. One day when he was in the most difficult part of the stream, a boy came blubbering up to him crying, 'Captain, Captain!'—'Well, what do you want?' 'Oh! do stop the boat, I've lost my apple overboard.'" The farmer saw the point of the story, and wisely concluded to collect his bill in the usual routine manner.

Taking it Coolly.

A not very skillful mason was employed to build an oven, which he completed in his usual style. The first time it was used, the whole structure tumbled into ruins, and the owner having found the mason, the following conversation occurred: "I have some news for you." "Ah! What is it?" "The oven you built for me has fallen down." "O that is nothing new—if it had fallen up that would have been news indeed." In spite of his vexation, the owner had to laugh at the mason's coolness, and left him, to seek a good workman to rebuild the oven.

A large number of Boys and Girls

have in past years secured various articles from our premium list. Young persons are often the most successful canvassers. We have in mind a boy who secured a sewing machine for his mother; another who got a wringing machine for his mother; and a school which recently obtained a melodeon for their Room, in the same way, for everybody was ready to help them. A liberal hearted gentleman paid the freight for them. These are only examples of what has been done, and may be done again.

A CURIOUS SIGN.—A correspondent writes to the *Agriculturist*: "In Yreka, the county town of Siskiyou County (one of the northern counties of California, and on the Oregon line) the following sign hangs with glaring letters in front of a baker's establishment, viz.: 'S. Gillig's, Yreka Bakery.'" At first sight this presents nothing remarkable, but upon examination it will be seen that the letters if read backwards, form exactly the same sign. Such a coincidence is extremely rare.

A CROOKED COMPANY.—A Hibernian sergeant was drilling an awkward squad of volunteers, and spite of all his efforts, failed to bring them into a straight line. At last, out of all patience he cried out, "Oh! what a bent row: just come out lads and look at yourselves."

PREMIUMS for 1864.

Or Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all—No Competition.)

Owing to the greatly increased cost of everything connected with publishing, and our determination not to raise the subscription price, and not to diminish the intrinsic value of the paper, but rather to improve it, we had expected to give no premiums hereafter, excepting the Great Strawberry which will be a premium to every subscriber, and ought to be enough to secure as many subscribers as could be desired. But the previous plan has worked well, and many of those who have obtained premiums hitherto, express a strong desire to have an opportunity to get some of the higher premium articles. After looking the ground all over, and making a careful estimate, we have decided to offer one general list, as named below. Any one desiring to do so, can go to work at once, and perhaps this very month get names enough for a good premium. All names sent in now, get the great strawberry plants and the two extra numbers. Note that five cents extra are needed when the "Agriculturist Strawberry" plants are desired, if to go by mail. This will, of course, be paid by the subscribers themselves.

The names (with money for each,) can be sent in as fast as gathered, so that the subscribers can begin to receive their papers. The premium will be paid to any one as soon as his list is completed. But, let it be distinctly noted, we can reckon for premiums ONLY those names which are marked as for Premiums, when they are sent in. Hereafter all the separate names thus sent and marked as for premiums, will be at once numbered in a special book, with the name of the sender, so that we can immediately turn to any canvasser's list, and see when it is full.

Premium clubs need not necessarily be all at one Post-Office. Each list ought to contain a fair proportion of new names, for it is to bring the paper before new subscribers, that the premiums are in part intended.

N. B.—Every article offered, is a good one—nothing second-hand or of poor make, or quality, or kind. We intend in all cases to deal fairly with every one, and esteem as special friends those who labor to promote the interests and circulation of this journal.

This list may perhaps be altered or amended from time to time, if circumstances or change of prices, etc., require, but all names sent in during any month, will be reckoned at the premium rates announced for that month.

Canvassers need not choose any particular premium until they get all the names they can. To avoid confusion, please send in the exact amount with each list of names. In special cases, the whole sum for a premium list may be forwarded, and the premium be received at once—the names to be sent in afterward.

No charge is made for packing or boxing any of the articles in this Premium List. The books and the Premiums K, to S, inclusive, are DELIVERED to any part of the United States and Territories, free of all charges. The other articles cost the recipient only the freight after leaving the manufactory of each. Every article is new and of the very best make.

Table of Premiums for 1864.

Names of Premium Articles.	Price of Premiums.	Names at \$1 each.	Names at 50 cts. each.

Descriptive Notes on the Premiums.

* BOOKS.—Any person sending in 20 or more subscribers, may select from our book list (page 317) to the amount of 10 cents for each name sent in at the club price of 80 cents, or to the amount of 30 cents for each name at \$1. (No books sent for less than 20 names). The premium books will be delivered anywhere in the United States, or to the border of the British Provinces, free of all

cost, by mail or express. Many Farmers' Clubs have, by means of this premium, obtained a good library.

A—Appleton's New American Cyclopaedia.—This magnificent work is now completed, and ready for immediate delivery. It consists of 16 heavy volumes, averaging 800 large two column pages, or in the whole work, 12,804 pages! (The books fill up over a yard of shelf-room.) It is in reality a complete library of itself, embracing full information upon every topic of human knowledge, alphabetically arranged for convenient reference. The subjects discussed number over twenty-five thousand! It is hardly possible to name anything upon which pretty full information may not be readily found in the Cyclopaedia. Many who can not purchase the work may be able to obtain it through our Premium offer. It is worth a year's effort in raising subscribers, though not a few may make up a club of 130 names in a brief time.

B—Best Clothes-Wringers.—This is a most excellent Household Implement, which should be in every family. It can be set upon any form of tub, and by turning with the right hand and picking up the garments with the left, they are pressed rapidly and easily between two elastic rollers, and drop out into a basket quite as free from water as they can be wrung by the hardest twisting by hand. Every lady knows that hand wringing is really harder upon the arms and shoulders than even the washing; while the twisting stretches the fibers with lever power, and hastens the wearing out. All this is avoided by the Wringer, which is in truth a *strength-saver*, and a *clothes-saver*. We have had one of the first imperfectly made instruments in weekly use for nearly four years, and it is as good as ever, while it has paid for itself many times over. A child can with this readily wring out a tub full of clothes. Our Premium Wringers are of the family size, and of the best manufacture, and are provided with cogs, and with springs, so that they will wring equally well any article from a blanket to a baby's stocking. The Wringer weighs only 15 lbs., occupies but a small space, and can be carried by hand, or sent by express, or as freight to any point, and is ready for instant use on removing the light packing box.

C—Nonpareil Washing Machine.—The best recommendation we can give of this, is, that while we have tried fifteen or twenty kinds, this is the only one that our "help" continue to use without being required to do so. It acts somewhat like the old "fulling mill;" the clothes are put into the hot water, and beat by two pounders which constantly turn them over. The beaters are moved alternately by a crank, provided with balance wheel which adjusts the force required so as to make the turning easy. Take it all in all, the Nonpareil is the best Washing Machine we have found. If we could find a better one, we should put it in our list, for anything that helps to reduce the hard work of washing day, is a godsend. The machine can go as freight, or by express to any part of the country, and we believe will give better satisfaction than any other yet brought out.

D—E—Sewing Machines.—We need not enlarge upon the benefits of Sewing Machines. They are doing more than all else to save the lives and health of females. It is no exaggeration to say that a woman can in a day do *ten times* as much ordinary sewing with a machine, as she can do by hand. We know many ladies who formerly employed a seamstress several weeks every year, but who now do all their family sewing, with less confinement and wear than when the common needle was their only resort. The interest on a fifty dollar Machine is only \$3 to \$4 a year, which is a small consideration compared to its advantages. Five hundred families ought to be supplied through our premium list this year. At least \$0 to 100 copies of the *Agriculturist* ought to be taken in every town, and would be if some enterprising man or woman would go round and gather them. Two or three ladies might join their efforts, and get a machine for use between them. We offer two kinds of Machines, both varieties of which we have had in use for several years, and with great satisfaction. They are both supplied with the Hemmer, and are sent out with full instructions for use.—The **Wheeler & Wilson Machine**, we have used during five years, and can bear full testimony in its favor. More of these machines are sold and used, we believe, than of all the other good kinds together, which is a strong proof of the satisfaction they give.—This sews with a double thread, both sides of the fabric showing the same stitch.—The **Wileox & Gibbs Machine**, we have used for over three years, and for most kinds of sewing it is excellent. It is very simple in its operation and can be worked by those who have the smallest amount of mechanical skill. It can be used for most kinds of sewing, and may well be adopted generally, at least where the higher priced machines can not be afforded. We know many who prefer this to any other.—For every kind of sewing, especially where the same stitch is required on both sides, we prefer the Wheeler & Wilson.

F—G—Woodruff Mercurial Barometer.—This is conceded to be the best and cheapest instrument for general use, which is now offered to the public. The peculiar form of mercury cup invented by Mr. Woodruff, renders the instrument far more portable than any thing previously made. The safe delivery of every instrument given by us as a premium, is warranted by the manufacturer (Charles Wilder, Peterboro, N. H.), when to be sent within 1,500 miles. The instruments are beautifully made, are about 3 feet long, and are sent direct from the factory, with no expense save the express charges which vary from 50 cts. to \$1.50, according to the distance. We offer two forms which differ mainly in the style of case, both being supplied with *Thermometer* and *Ventilator*. The \$12 form is of course more ornamental, and the more desirable instrument, though either of them is highly valuable. A barometer is to farmers or others on land, what it is to sailors at sea—an indicator of the weather to be looked for. There are many times every year when the indications of the barometer in regard to the weather, will often be of more value than its whole price, while the interest on its cost would be less than half a dollar a year.

The habit of observation, and of scientific study cultivated in a family of children where a Barometer is used, is a valuable consideration.

H—The Aquarius.—This is an excellent little portable force-pump, useful in many ways. One can take this instrument in his hand with a pail of water, and throw a considerable stream to any point where a fire may be breaking out, and do more to quench it, than he could with a dozen pailfuls dashed on, even if the fire could be reached. We have thrown water from the ground up against the third story windows of a house. The Aquarius is very useful for watering gardens, for washing windows, carriages, etc., etc. It is provided with rubber suction pipe, to draw water from a pail, tub or bucket, and an ejection pipe having both a nozzle for throwing a stream, and a rose or sprinkler. It has also an air chamber for giving a constant stream. It is a handy instrument, for every household, aside from its benefit as a fire engine with which many an incipient fire has been subdued.

I—J—Melodeons.—None need be told of the pleasure given by a good Melodeon in a household, or of its utility in the Week Day and Sabbath School Room, and the Church. "Music hath charms to soothe even a savage breast," and we hesitate not to say that a benign influence is exerted upon every house and school room where a Melodeon or other good musical instrument is found.—We offer two sizes in our list above, and those of a different price may be selected for a proportionate number of subscribers. (For sizes, style, prices, etc., send a stamp to George A. Prince & Co., Buffalo, N. Y., and get one of their illustrated descriptive Catalogues, which will be sent free.) We have used one of these Melodeons during four years past, and it continues to give the highest satisfaction. It has not been tuned or otherwise repaired in all that time. The premium instruments will be shipped direct from the manufacturers at Buffalo, ready boxed. They can go by railroad, steamboat, express or otherwise, as desired by the recipient. It will be an easy matter for Churches, and both Week Day and Sunday Schools to unite their efforts and secure an instrument for the public use.—Many have done so already.

K—Q—Seven Volumes of the Agriculturist.—Here is a whole *Agricultural, Horticultural, and Household Library*, embracing also a large amount of interesting reading for Children and Youth, and thousands of instructive and pleasing engravings. Each volume contains more printed matter than half a dozen dollar books of the usual size. There are in each volume from one to two thousand articles and condensed items, among which every reader will find something useful to himself and family. We send them post-paid (as in the above table), in new clean numbers, printed from stereotype plates as needed. The last number of each volume contains an index to the whole volume. (Any person preferring them bound, can receive them in this form, neatly done, at an expense of 65 cents per volume, for the cost of binding, and extra postage required when mailed in this form—or if called for at the office, or sent by express, or otherwise, if not to be prepaid, at a cost of only 25 cents per volume.) Let every one selecting this premium be sure to name what volumes are desired, or how many of each, as duplicates of any number can be chosen if preferred.—We can only supply from volume 16 to volume 22 inclusive. The previous volumes are not stereotyped.

R—Best File for the Agriculturist.—Jacob's Portfolio file, made just to fit the *Agriculturist*, with the name of the paper gilded on, is exceedingly convenient. It is a neatly embossed or stamped cover, made so that each successive number of the paper can be inserted in a minute, when it is strongly held in. The numbers thus fastened together are as convenient as a bound book. When one volume is completed, it can be removed and stitched together, and the numbers of a new volume be inserted. A single cover will answer for a dozen or twenty successive years. It is without doubt the most perfect paper file yet made. It is sent post-paid, as above.

S—Water Color Paints.—Those offered (Osborne & Hodgkinson's) are the best of American Manufacture, and though not so fine for artist's work, as some of the imported (which now sell at six times the price), they answer very well for common sketching, particularly by children and beginners. They are especially useful to children, as their use tends to develop a taste for form and color, and skill in the use of the pencil. We send them post-paid, in a neat mahogany case containing 24 small cakes of assorted colors, with brushes, etc.

T—U—Premium Plows.—The two named in the table above (*Cylinder and Eagle No. 20*), are two of the best farm plows in use, and will doubtless give ample satisfaction to any one securing them as premiums. We have not space for a particular description. The Eagle Plow is well-known. The working of the Cylinder Plow, and other items concerning it are described on page 136 of Volume XX, (May 1861).

V—W—Hay and Straw Cutters—Steel-toothed Cultivators.—These implements are of first importance to all farmers, some of whom may find it most convenient to secure them through our premium list. We send the best implements we know of at the prices named.

X—Family Lard and Wine Press.—This is a very convenient Household implement for pressing out lard or tallow, the juices of Grapes, Currants, Berries, etc.

Other Premiums.—We have on trial several other articles, and expected to offer more of them this month—but those most carefully experimented with, did not prove good enough to be strongly commended. Other new articles are on trial—some of which may be offered next month. A new Apple Parer was decided upon, but we can not yet get the promise of a supply. Any future premium articles will be offered on similar terms to those in the table above, these terms being the most favorable possible.—We still solicit further suggestions from subscribers in regard to what would be most desired in the Premium List.

The Markets.

AMERICAN AGRICULTURIST OFFICE.

We present above a series of tables prepared expressly for the *American Agriculturist*, which give, in a very condensed and convenient form for study and reference, the various transactions in Breadstuffs, not only during the past month but for a series of years past. The figures are compiled from an immense number of records, partly from official sources and partly gathered by ourselves. These figures are believed to be very reliable, as no labor or care has been spared to make them perfect. The tables tell their own story so plainly that there is little necessity for explanatory remarks.—Table 1 shows that, excepting in barley, the Receipts at this Port have been less than during the previous month—oats falling off one half. The Sales of Wheat, Flour and Corn have been large.—Table 2 shows a similar falling off in receipts when comparison is made with the same time last year; the falling off in wheat and oats has been very marked. The smaller Receipt is noteworthy.—The Exports (table 3), are also considerably less this year than last.—Tables 4 and 5, show that while the exports for the grain year, ending Sept. 1, were somewhat less than for two years previous, yet they were much larger than in any year between 1847 and 1861. This enormous export of our breadstuffs during each of the past three years (tables 4 and 5), have had a very benign effect upon the finances of our country. Every bushel of wheat or grain exported has saved the export of its value in gold, and has in reality added so much to our aggregate national resources. We can hardly hope for the continuance of so favorable a state of things during the next ten or twelve months, as our advices from abroad show positively that the foreign harvest has been very good, and less of our breadstuffs will therefore be needed. Still, Great Britain never produces enough to supply the home consumption, and as we can furnish breadstuffs cheaper than any other country, there will doubtless continue to be fair shipments of our surplus, which is

considerable, as we have old stocks of wheat on hand, and the past harvest was fully an average one. We had reports of serious disaster to the growing corn by frost, on the closing nights of August, but later accounts show that though the injury was considerable, it was far less extensive than the first newspaper reports indicated. The drouth still prevailing in some sections will further reduce the yield, yet on the whole there will be a fair crop of corn—perhaps nearly an average one, taking the whole country together, if no further casualty occurs. With the remaining stock in the country from last year's crop, there is not the least danger of a scarcity. . . . The Breadstuffs markets in this city were less freely supplied and were quiet during most of the past month,—prices fluctuating frequently. Recently rather more favorable market news from Europe, and a rise in Gold and Sterling Exchange, encouraged export buyers, and heavier purchases have been made, the market closing buoyantly. . . . Cotton has been in fair demand,—falling off in price early in the month, but closing at rising rates. The stock here on the 1st inst. was only about 15,000 bales. . . . Provisions have been quite plenty, and prices have been unsettled. The demand has not been very active. . . . Tobacco has been more sought after, owing to the frost reports, and has been held with more firmness. . . . Wool has been in brisk request, particularly within the past ten days, chiefly for manufacturing purposes, especially army cloth-contractors having made very heavy purchases. Prices are firmer and advancing. . . . Hay, Hops, and Seeds have been in more demand. . . . In most other agricultural products, transactions have been moderate. The annexed table will show the changes in prices, since our last, and also the closing quotations.

CURRENT WHOLESALE PRICES.

PEAS, per bushel.		5 00

N. Y. Live Stock Markets.—The Cattle markets have been abundantly supplied with animals during the past month, the average being 5,669 per week. At the first market after our last report, with 4,657 offered for the week, prices advanced ¼c., and the stock sold off rapidly. The following week there were 5,820 on sale, and prices fell off ¼c.; cattle about all sold. At the next market 5,194 cattle were offered, and all found purchasers at nearly ¼c. advance. The week ending Sept. 15th brought the largest number of cattle ever seen in New-York and vicinity, for a single week. They footed up over 7,000 head, and nearly all found purchasers, though prices were ¼c. lower than at the previous market. A small number of the best cattle brought 11c. per lb. for the estimated dressed weight; good steers, 9½c. @ 10c.; common cattle, 7½c. @ 8½c.; and some very poor steers, dry cows, etc., sent in on account of the dry

pastures, went at 6c. @ 6½. Average of all sales about 9½c.

Milk Cows.—About 100 per week are now offered at the regular yards. The demand is not brisk; common to good fresh milkers sell at \$30 to \$40 each; first class \$45 to \$50; fancy animals, at higher figures.

Sheep and Lambs.—Receipts have averaged 15,890 per week for a month past, which is a great increase over the previous month. They have been selling well, and just now there is a large demand for store sheep to winter over. Good fat sheep are worth, for butchering, 5c. per lb., live weight; common sheep, 4½c. Lambs are abundant, and sell slowly at \$2½ to \$3½ each.

Live Hogs.—Are in pretty good demand, at 5½ @ 5¾c. per lb., live weight, for corn-fed; and 5½c. @ 5¾c. for distillery hogs. Receipts average 9,506 per week for a month past.

The Weather.—For a month past has been hot and very dry. From Aug. 17th, to Sept. 18, less than one inch of water fell, all told, the most of this inch on the night of Aug. 29th. Pastures and meadows are drying up, and the buckwheat crop will doubtless be short. Early sown winter grain will hardly vegetate until we have rain. Our daily notes, condensed, read: August 19, to 24, clear and hot—25, cloudy, P. M., slight shower at night—25, N. E. rain A. M., clear, cool, P. M.—27, clear cool—28, light rain—29, clear and fine A. M., cloudy P. M., with rain at night—30, clear, cool, with hard frost in some portions of the West—31, clear, cool, fine—September 1, cool, light rain—2, to 10, clear, fine, moderately cool, getting dry—11, clear A. M., cloudy P. M.—12, 13, light rain, but not enough to do any good—14 to 16, clear, dry, warm—17, passing clouds and shower at night.

Rain Fall for August 4.59, most of which fell before the 12th. The Barometer has marked a pretty even track—from 29¾ inches to 30¾ inches.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit).—r indicates rain—s, snow.]

To Sunday School Teachers and Others.

The Book of "Lessons for every Sunday in the Year," has given a satisfaction, and met with a success far beyond any one's expectation. It was at first written on a plan prepared by the Editor of the *Agriculturist* for his own School, and the copyright was freely given away to others who undertook to supply the public demand that sprung up. It has been adopted and used generally in the Sunday Schools and families of almost all Christian Denominations alike. Nearly or quite one hundred thousand copies have been sold by the different Publishers and S. S. Depositories, within the present year. Successive editions published at the *Agriculturist* Office alone, have run up to full twenty thousand copies. The following editorial, which we have learned is from the pen of John Hart, L.L.D., the well-known Teacher of Philadelphia, and Editor of the Sunday School Times, will indicate the reception the book has met with:

From the Sunday School Times (Philadelphia,) March 14.

"A NEW QUESTION BOOK.—We have just been examining a little book published by Orange Judd, (of New-York City,) called 'Lessons for Every Sunday in the Year,' and have risen from the examination with a feeling of thankfulness that such a book has been made. We have never seen a Question Book containing so many conveniences and advantages as this, so many excellences, both positive and negative. Mr. Judd is a life-long Sabbath-school man, and this book has been the fruit of the experience of himself and some of his friends in trying to meet the practical wants of the Sabbath-school. Like all good text books, it has grown out of actual necessities and experience; it is a growth rather than a work. We advise every Superintendent to send at once for a copy."

The Book can be obtained at the *Agriculturist* Office in large or small quantities, at the uniform price of 10 cents per copy. If to go by mail, the postage to be pre-paid, is 3 cents each copy in packages of ten or more. Two postage being rated by the 4 ounces, under the new law, the price for less than ten pre-paid by mail is:

1 copy, 11 cents.	4 copies, 52 cents.	7 copies, 80 cents.
2 copies, 28 cents.	5 copies, 66 cents.	8 copies, 104 cents.
3 copies, 42 cents.	6 copies, 80 cents.	9 copies, 118 cents.

Business Notices.

Eighty Cents a Line of space.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It requires no focal adjustment, magnifies about 100 diameters or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for \$3, or with 21 objects for \$5. Address HENRY CRAIG, 180 Centre-st., New-York. A liberal discount to the trade.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month. TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY. Fifty cents per line of space for each insertion. One whole column (145 lines), or more, \$50 per column. Business Notices, Eighty cents per line of space.

FOR THE GERMAN EDITION ONLY. Ten cents per line of space for each insertion. In both English and German, Fifty-five cents per line. One whole column (130 lines), or more, \$10 per column. Business Notices, twenty cents a line.

Wanted.

either examine our stock or communicate with us. Catalogues
sent to applicants. STEPHEN HOYT & SONS.

New Canaan, Ct., August 19th, 1863.

FRUIT AND ORNAMENTAL TREES.

RARE CHANCES OFFERED.

200,000 Choice Fruit Trees, Vines, etc., for
sale, of varied size to suit customers.

The subscriber calls attention to his unusually large stock
of well grown trees now on hand, and especially to the present
stock of the SWANZIE FRUIT, which is the largest and
finest ever offered at these Nurseries.

With twenty years of experience, by careful observation
and judicious selections, he believes he is able to judge and
furnish what will suit his customers, as well as the varied
soils and localities, in which trees may be wanted. There is
also special attention paid to local varieties, adapted to
Southern and Central Pennsylvania, many of which have
proven themselves more valuable than sorts originating in
a climate differing so widely from these sections.

He is also preparing a list of CLUB PRICES for those who
purchase direct from the proprietor, offering rare inducements
for neighbors to join together and get trees considerably
under the regular retail prices.

This mode is adopted by those who may not have an op-
portunity to purchase from his regularly authorized agents,
and hold a mistrust towards the too numerous tree vendors
spread over the land.

The frequent use made of his name and establishment
by strangers, to effect sales where the reputation of the
nursery is known, compels him to warn all not to purchase
—as coming from these Nurseries—stock offered by pre-
tenders, who do not hold an authority from the proprietor.
Local or stationed agents will be accepted, but neither
traveling nor stationary agency inquiries will receive notice,
unless the parties produce satisfactory reference as to their
honesty in dealing with customers and employer. Send for
Catalogues and priced List, which contain inducements not
before offered by him. ADDRESS AND TRUSTWORTHY RE-
FERENCE WILL BE FURNISHED TO ALL WHO ARE STRANGERS
TO THE ESTABLISHMENT.

Address DAVID MILLER, Jr.,
Cumberland Nurseries, Carlisle, Pa.

THE NEW EARLY GRAPE, THE ADIRONDAC,

For sale by

J. W. CONE, Norfolk, Ct.

The Adirondac is an early grape of rare excellence, re-
sembling the celebrated hot house grape Black Hamburg.
Skin thin and brittle, almost pulpless and very sweet, ripens
from one to two weeks before the Delaware or Hartford
Prolific, is double the size of the Delaware, hardy, prolific
and a vigorous grower, has a perfectly melting juice with a
flavor of the most delicate and excellent character.

SEND FOR A CIRCULAR AND PRICE LIST.
Mr. J. W. Cone of Norfolk, Ct., is my General Agent for
the sale of the Adirondac Grape Vines in the State of Con-
necticut, and will be prepared to supply all orders both at
wholesale and retail.

J. M. THORBURN & CO.,
Importers and Growers of Seeds,
15 John-street, New-York.

Delaware Grapes.

After some years of experiment, the subscribers have
adopted a mode by which they can produce plants of this
valuable grape with abundant fibrous roots at the following
very low rates:

1st Class, \$25 per 100.	2nd Class, \$15 per 100.
\$200 per 1000.	\$100 per 1000.

Of these one year old, they can furnish 50,000 deliverable in
October and November.—These vines are not grafts, but
are raised direct from cuttings.

Those who wish to plant largely will do well to examine
this Stock before purchasing, and to send their orders early
as the demand last year exceeded the supply.

Those who wish can also see THREE ACRES of Dela-
ware Vineyard in full growth.

CONCORD and other Grapes furnished by the 100 or 1000.
Address PARSONS & CO.,
Flushing, N. Y.

chester, Pa.

DUTCH FLOWER ROOTS.

B. K. BLISS,

Seedsman and Florist.

SPRINGFIELD, MASS.

Would respectfully inform his friends and patrons of the arrival of his annual importation of **Bulbous Roots**, and is pleased to say that they are particularly fine this season. This selection has been made with great care from one of the oldest and most respectable growers in Holland, and can be recommended with confidence, as being in every way worthy the attention of Amateurs and others interested in their culture. The stock comprises all the most desirable varieties of

Hyacinths, Double and Single. **Tulips**, Double and Single, Early and Late. **Crocus**, all of the old, and many new varieties. **Crown Imperials**. **Polyanthus**. **Narcissus**. **Double Roman and Paper White Narcissus**. **Jonquills**, Double and Single. **Japan Lilies**. **Ranunculus**. **Anemones**. **Arum**. **Snow Drops**. **Iris**. **Grape and Musk Hyacinths**, &c., &c. A descriptive priced Catalogue of which, with full directions for culture, will be forwarded to all applicants on receipt of a three cent postage stamp.

Bulbous Roots by Mail.

Post-paid to all parts of the Union, where there is postal communication.

THE NEW POSTAGE LAW authorizes the sending of **BULBS**, **PLANTS**, **ROOTS**, **CUTTINGS** and **SEEDS** by mail, upon pre-paying the postage at the rate of two cents for every four ounces in weight. To meet the wishes of those who reside at a distance, we have prepared the following collections with full directions for culture, which will be sent by mail post-paid, or by Express, as the purchaser may direct, at the prices affixed.

COLLECTION No. 1, by Express \$20, by Mail \$22, contains 50 Double and Single Hyacinths, 60 Double and Single Tulips, 24 Narcissus, 5 Crown Imperials, 12 Jonquills, 150 Crocus, 5 Peonies, 4 Japan Lilies, 13 Iris, 25 Ranunculus, 25 Anemones, 20 Hardy Gladiolus, 4 White Lilies, 1 Lillium longiflorum, 1 Lillium croceum, 12 Hyacinths.

COLLECTION No. 2, by Express \$10, by Mail \$11, contains 25 Double and Single Hyacinths, 35 Double and Single Tulips, 12 Narcissus, 2 Crown Imperials, 6 Jonquills, 75 Crocus, 2 Peonies, 2 Japan Lilies, 6 Iris, 12 Ranunculus, 12 Anemones, 6 Hardy Gladiolus, 2 White Lilies.

COLLECTION No. 3, by Express \$5, by Mail \$5.50, contains 10 Double and Single Hyacinths, 20 Double and Single Tulips, 6 Narcissus, 1 Crown Imperial, 3 Jonquills, 36 Crocus, 1 Peony, 1 Japan Lily, red, 4 Iris, 6 Ranunculus, 6 Anemones, 6 Hardy Gladiolus.

COLLECTION No. 4, by Express \$3, by Mail \$3.25, contains 6 Double and Single Hyacinths, 20 mixed Tulips, 6 Narcissus, 20 Crocus, 3 Hardy Gladiolus, 1 Japan Lily, white.

The different varieties in the above collections will embrace all the various colors.

For a more particular description of the collections, see Catalogue.

All of the Bulbs named in the Catalogue will be mailed post-paid at the prices quoted, for orders amounting to \$1.00 and upward, the freight on all parcels by Express, to be paid by the purchaser. B. K. BLISS, Springfield, Mass.

TOBACCO.

Just How to Grow it.

Every particular, from the selection of the Seed, and preparation of the ground, to the Gathering, Curing and Marketing the Crop, is given in a work issued by the Publisher of the *American Agriculturist*, and sent post-paid for 25 cents. This work consists of a selection of the best fourteen out of eighty-five Essays, prepared by eighty-five different cultivators, residing in various parts of the Northern and Middle States. In each of the Essays contained in this work, the writer tells, in a plain, practical, straight-forward manner, just what to do, and how to do it. Any item omitted by one is given by another, so that the information is full and complete. Several engravings illustrating the method of drying, packing, etc. The work is worth its weight in silver to every one growing even a small plot of tobacco.

**A RELIABLE AGENCY
FOR PURCHASING
ARTICLES OF MERCHANDISE,
Implements for the Farm,
Garden and Household,
SEEDS, &c.**

70 & 71 West Washington Market.**

**MUNN & CO'S
ESTABLISHED 1842**

During the past Twenty Years, Messrs. MUNN & CO., in connection with the publication of the WEEKLY ILLUSTRATED SCIENTIFIC AMERICAN, (the only paper devoted to the Mechanical Arts in the Country), have acted as Attorneys for procuring Letters Patent in the United States and all foreign countries.

They would state that they have acted, during this period, as agents for more than

Twenty Thousand Inventors!

In fact, they have become identified with the whole brotherhood of inventors and patentees, at home and abroad. Thousands of inventors for whom they have taken patents, have addressed to them most flattering testimonials; and the wealth that has inured to the inventors whose patents were secured through their Office, and afterwards illustrated in the SCIENTIFIC AMERICAN would amount to many millions of dollars!

Messrs. MUNN & CO. never had a more efficient corps of Draughtsmen and Specification Writers than those employed at present; and they are prepared to attend to patent business of all kinds, in the quickest time and on the most liberal terms.

For further information, send for a pamphlet which contains the Patent Laws of the United States, and much other valuable information of importance, to inventors and all others who own patent property. Also pamphlets of information furnished regarding the Patent Laws of all Foreign Countries.

For further particulars address MUNN & CO., 37 Park-row, New York; or corner F and 7th streets (opposite Patent Office), Washington, D. C.

THE EUREKA FEED CUTTER.

A Cutter adapted to the wants of Farmers.

FIRST RATE FOR
CORN STALKS,

HAY and STRAW

This machine has important improvements. It CRUSHES and CUTS the heaviest corn stalks, and hay and straw with great rapidity, by either hand or horse power. It has four cylindrical knives, ground on the inside; they cut with the SHEAR CUT, and can be EASILY ground and kept in complete cutting order by ordinary farm help. It is well made, easily operated, simple, durable, and effective. Hundreds are in actual operation to the perfect satisfaction of the purchasers. Orders solicited—promptly attended to. Send for a circular, furnished FREE. Manufactured only by

H. K. PARSONS, AGENT,

Novelty Works, HARRISBURG, PA.

\$—SOMETHING NEW! AGENTS WANTED.

PRODUCE OF ALL KINDS BOUGHT.

Mode of applying JOHN'S & CROSLEY'S GUTTA PERCHA CEMENT ROOFING.

This Roofing is Fire and Water Proof, and can be applied by any ordinary laborer. It costs only about one-third as much as tin, and is more durable.

GUTTA PERCHA CEMENT PAINT applied to leaky roofs of all kinds, will render them perfectly water-tight. It is put up ready prepared for use and for shipment to all parts of the country. This Paint is particularly adapted for painting Out-houses, Barns, Fences, &c., &c., and will effectually prevent wood from decaying.

These materials have been tested on more than twelve thousand roofs during the past six years, and we can give abundant proof of all we claim for them. Full descriptive circulars and any required information furnished by the

JOHN'S & CROSLEY MANUFACTURING CO.,
73 William-st., cor. Liberty, New-York.

GREAT DIS-
COVERY!

USEFUL and VALUABLE DISCOVERY!

HILTON'S INSOLUBLE CEMENT!

Applicable to
the useful Arts.

Is of more general practical utility than any invention now before the public. It has been thoroughly tested during the last two years by practical men, and pronounced by all to

Be Superior to any
Adhesive Preparation known.

Hilton's Insoluble Cement

Is a new thing, and the result of years of study; its combination is on

SCIENTIFIC PRINCIPLES,

And under no circumstances or change of temperature, will it become corrupt or emit any offensive smell.

Boot and Shoe
Manufacturers

Boot and Shoe Manufacturers, using Machines, will find it the best article known for Cementing the Channels, as it works without delay, is not affected by any change of temperature.

Jewelers.

Jewelers will find it sufficiently adhesive for their use, as has been proved.

Families.

It is especially adapted to Leather, and we claim as an especial merit, that it sticks patches and Linings to Boots and Shoes sufficiently strong without stitching.

It is a Liquid.

IT IS THE ONLY LIQUID CEMENT

Extant, that is a sure thing for mending Furniture, Crockery, Toys, Bone, Ivory, and articles of Household use.

REMEMBER

Hilton's Insoluble Cement is in liquid form and as easily applied as paste.

Hilton's Insoluble Cement

Is insoluble in water or oil.

Hilton's Insoluble Cement

Adheres oily substances.

Supplied in Family or Manufacturers' Packages from 2 ounces to 100 lbs.

HILTON BROS. & CO.,

PROPRIETORS,
PROVIDENCE, R. I.

Life Insurance.

THE MANHATTAN LIFE INS. CO.
OF NEW-YORK, No. 31 NASSAU-ST.

Accumulation \$1,500,000.
Claims paid \$30,000.
Dividends 700,000.

The greatly superior advantages of this old established Company, can be ascertained free of expense at any of the agencies, or by writing to the home office for a prospectus.
J. L. HALSEY, Ast. Sec'y. HENRY STOKES, President.
S. N. STEBBINS, Actuary. C. Y. WEMPLE, Secretary.

SULPHITE OF LIME,

Used for preserving cider and all kinds of wine. Prepared and sold in bulk or in Cans of 10 oz. each, with directions by GAIL & SCHLEICHER, Manufacturing Chemists,
West Mount Vernon, New-York.

Depot, 103 Maiden Lane, N. Y. City.

RUSSIA OR BASS MATS, SELECTED EXPRESSLY for hudding and tying: GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for Nursery purposes, for sale in lots to suit, by
D. W. MANWALING,
Importer, 243 Front-st., New-York.

UNIVERSAL CLOTHES WRINGER.

This popular machine sells rapidly wherever offered.

Every Family will have one!

It is only a question of time. Thousands of families every month are being relieved in the hardest of all household work, WASHING. Thousands of dollars are daily saved by pressing the water and dirt out of the clothes, instead of twisting and wrenching the fabric, and destroying the garments.

Cotton is Expensive,

Save it by using the Universal Clothes Wringer.

"Time is Money."

ORANGE JUDD, Esq., of the American Agriculturist, says: "A child can readily wring out a tubful of clothes in a few minutes." Therefore use the U. C. W., and save time and money.

Ladies who have long used them and know their value, speak in the highest terms in their praise. One says—"I would as soon be without my cow, as without my wringer." Another, "I can now go to bed and sleep after washing-day." Another, "I had to pay fifty cents for a washwoman before, and now we do it ourselves." Another, "The rich may afford to do without them, but I could not." &c., &c. These are but a few among thousands. Every one using them will report likewise.

We have seven sizes, from \$5 to \$30. Those suitable for ordinary family use, are No. 1, \$10, and No. 2, \$7. These have

COG-WHEELS,

and are WARRANTED in every particular. This means especially, that after a few months' use, the lower roll

WILL NOT TWIST ON THE SHAFT,

and tear the clothing, as is the case with our No. 3 (\$5), and other wringers without Cog-Wheels.

In April's sales of over 5,000, only 27 were of the No. 3, \$5, size, without Cogs. In our retail sales we have not sold one in over a year! This shows which style is appreciated by the public. This is the only wringer with the

PATENT COG-WHEEL REGULATOR,

and though other wringer makers are licensed to use our rubber rolls, yet NONE ARE EVER LICENSED to use the Cog-WHEELS. Therefore, for cheapness and durability, buy only the

Universal Clothes Wringer.

On receipt of the price, from places where no one is selling, we will send the U. C. W., FREE OF EXPENSE. What we especially want is a good

CAN VASSER

in every town. We offer liberal inducements, and guarantee the exclusive sale. Apply at once to

R. C. BROWNING,
347 Broadway, New-York.

MASON & HANLIN'S CABINET

ORGANS—One to twelve stops; prices \$70 to \$600. A vast improvement on everything of the Melodeon or Harmonium kind. See written testimony of more than one hundred of the most eminent artists and organists of leading cities to the great excellence of these instruments, and the superiority to all others of their class for private and public use. Also, Melodeons from \$80 to \$170 each. Illustrated Catalogues sent free. Ware rooms Nos. 5 and 7 Mercer st., New-York. Address MASON BROTHERS.

TRUSSES.—RADICAL CURE OF HERNIA OR RUPTURE.—DR. S. N. MARSH, of the well-known house of Marsh & Co., No. 2 Vesey-st., Astor House, opposite the church, devotes special attention to the surgical adaptation of his trusses. Also every kind of Trusses, Supporters, Shoulder Braces, Elastic Stockings, and Mechanical appliances for Deformities. (A lady attendant.)

LANE'S PATENT CARRIAGE JACK.

CONVENIENT,
SIMPLE, and
CHEAP.

This Jack is made to operate on a new principle, and is pronounced by those who have used them, as the most convenient article of the kind before the public. For sale by the principal hardware and agricultural dealers, also by the general agent A. H. HAVILAND, 261 Pearl-st., New-York, and the manufacturer J. G. LANE, Washington, N. Y. SEND FOR CIRCULAR.

HORSE POWERS, TRESHIERS

AND SEPARATORS, CLOVER HULLERS, FANNING-MILLS, HICKOK'S PATENT CIDER MILL, HUTCHINSON'S PATENT CIDER AND WINE MILL, WINE PRESSES, ALLEN'S and other Patents, POTATO PLOWS, FRUIT GATHERERS, FRUIT LADDERS, &c., &c.

R. H. ALLEN & CO.,

139 & 191 Water street, New-York.

The NONPAREIL WASHING MACHINE

Is the only entirely reliable machine in use. It has been before the public two years, and has not in any instance failed to give satisfaction.

It saves two-thirds the labor and time required in hand washing.

It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it.

It will not get out of order.

It is recommended by Mr. Judd, the proprietor of this Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20.

Send for free Circular to

OAKLEY & KEATING, 73 South-st., New-York.

AGENTS

WANTED EVERYWHERE TO SELL WOODRUFF'S PATENT PORTABLE BAROMETERS.

CHARLES WILDER, Peterboro', N. H.

TO FARMERS.

Bone Taseu.

Bone Taseu.

MANUFACTURED BY THE LODI MANUFACTURING CO.

The large sale of this manure, and constantly increasing demand has induced the Company to arrange for its manufacture on an extensive scale.

It is composed of FINE RAW BONE and NIGHT SOIL, free from all impurities, dried and ground to a fine powder, making it quick in its action, as well as permanent in its results.

For Buckwheat, Turnips and Winter Grain, no manure can be found of equal value for the amount invested.

It is put in new Barrels, 200 lbs. in each. One and a half barrels will manure an acre.

Price, free of cartage, \$1.50 per Barrel.

All orders, which will hereafter be filled promptly, must be directed to the LODI MANUFACTURING CO.,
66 Cortlandt-st., New-York.

TO FARMERS

AND OTHERS.

We are manufacturing a Genuine Article of VERY FINE, BONE DUST, and RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash.

Address

A. LISTER & BRO.,

Newark, N. J.

PURE BONE DUST.

COE'S SUPERPHOSPHATE OF LIME,

AND ALL OTHER RELIABLE FERTILIZERS.

In quantities to suit purchasers.

R. H. ALLEN & CO.

139 & 191 Water street, New-York.

BRUCE'S

CONCENTRATED MANURE.

Farmers wishing this valuable manure, will please send in their orders early for the fall crops. Sold at the old price, \$40.00 per ton. For Wheat, Rye, and Grass lands it has no equal. Send for a Circular, containing testimonials and directions for use.

C. W. VAN DOREN & CO.,

58 Cortlandt-st., New-York.

AMMONIATED PACIFIC GUANO.

A real guano containing from seventy to eighty per cent of Phosphate of Lime, to which has been added, by a chemical process, a large percentage of Actual Ammonia so fixed that it can not evaporate, making it equal if not superior to any other fertilizer.

Pamphlets with copies of Analysis by Dr. Jackson, Mass. State Assayer, and testimonials from scientific Agriculturists showing its value can be obtained from
J. O. BAKER & CO., Selling Agents,
81 Wall-st. New-York.

A GREAT "Baker's Dozen." Fourteen for Twelve.

We want a large number of new readers to see, and get acquainted with the *Agriculturist* before January, for those who do so, will generally bring along other new readers to begin with the next volume. For this reason, and as a special bounty, we make the following offer:

Every new name arriving on and after October 1st, will be at once entered on our books to the end of 1864, and receive not only volume 23 complete, but also the remaining numbers published this year—all for a single year's subscription—if the name is distinctly stated to be a new one, as noted below.)—Thus:*

New Subscribers for 1864, received during October, will get the paper for November and December, of this year, FREE.—(14 months for the price of 12.)

Those received during Nov. will get December FREE.

N. B.—The above offers extend to *all* new subscribers, whether they are received singly, or in clubs, or on premium lists, or from Agricultural Societies, or otherwise.

*N. B.—Since many old subscribers are renewing in advance, it is important that *new subscribers' names* be marked as "NEW" when sent in, if the extra numbers are desired, for we shall not send these extra numbers unless they are specially and definitely asked for.

GOOD PAY is offered to those who collect Clubs of Subscribers. See page 313. This is a good time to get them; the above "Baker's Dozen," and the Strawberry Premium, will aid canvassing now. See next item.

THE GREAT STRAWBERRY is for *all* Subscribers for 1864, who apply in accordance with terms. Read the terms carefully through, on page 259. The substance of these terms, is, that the great "Agriculturist Strawberry" is being multiplied as rapidly as possible, and the plants produced will be distributed free next year, as far as they go, beginning with the names in the order of application and entry on our books for 1864. Those to receive the plants by mail will need to send, in addition to the subscription, 5 cents to pay for oil-cloth and postage on the plants. We hope to have plants for all who receive the *Agriculturist* for 1864. No distinction will be made between old and new subscribers.

Postage on the Agriculturist is only 3 cents per quarter, if paid in advance by the recipient. The old dispute about the weight, is settled by the new law which allows 4 ounces instead of 3; no copy weighs 4 ounces in any case. Any postmaster who insists upon charging more than 1 cent per number, when paid quarterly or yearly in advance, is either too ignorant to hold office, or is guilty of extortion. We ask the name of any one who hereafter exacts more than the above amount of postage, as has been illegally done hitherto, in some cases. The new law is too plain to admit of doubt.

Specimens or Extra Numbers are costly, and each copy requires two cents postage paid in advance. So they cannot be scattered around very freely. When needed for canvassing, the judgment of the applicant will in each case decide whether both the paper and the postage should be at the expense of the Publisher. Except when to be used solely for *our* benefit, the postage at least should be provided for.

CLUBS can at any time be increased, by remitting for each addition the price paid by the original members, if the subscriptions all date at the same starting point. The back numbers will of course be sent to added names.

A Pleasurable Announcement.

Our readers will doubtless be greatly pleased to learn of the return of Mr. Mason C. Weld, to resume his labors in the *Agriculturist* Office. A year ago he was temporarily called away, on short notice, to an important place in the country's service, and, as Lieut. Colonel of the renowned 25th Regiment Connecticut Volunteers, he has taken an active part in the restoration of Louisiana, and in the reopening of the Mississippi by the capture of Port Hudson. His regiment having served out their time and received their honorable discharge, Mr. Weld will immediately enter upon the more peaceful labor of gathering and spreading information through the columns of this journal.—Our good Agricultural Ship has never before been so well "manned" as it is now to be. With the constant and earnest editorial labors of Prof. Thurber and Lieut. Col. Weld, both of whom have had the most thorough practical and scientific training for their profession, also of Messrs. Fitch and Taber, who have long been engaged in the office, and with the efficient editorial aid of Mr. Clift, Mr. Gridley, and several other practical and intelligent observers in different parts of the country, in addition to a widely extended circle of voluntary correspondence, we feel justified in promising a still further large advance in the intrinsic value of the *Agriculturist*. Our aim is, to condense into these pages the largest possible amount of useful and reliable information upon all topics relating to the labors of the Farm, Garden and Household. To this end we shall continue to enlarge the working force. The more thought and labor we can concentrate upon the paper, the more valuable will every line become to the reader. It is not too much to say, that nowhere else can one obtain in the same space, or for so little money, so much of really valuable information. We take no little pride and pleasure in contrasting the present facilities of this journal, with what they were ten years ago when the writer was almost literally "captain, mate, and all hands."

Our thanks are due to an appreciating circle of readers, now close on to eighty thousand, and soon to be a hundred thousand, we hope.—As the circulation enlarges, we are able to make further improvements, without increasing the cost to the reader.

We bespeak a continuance of the favor so generously bestowed, and promise to spare no expense or effort to merit it in a still greater degree. Will our present readers each gratify us, at this time, by a word to friends and neighbors, informing them of what are the plans and aims of the publisher, and how useful and interesting the paper may be to them. We would like to begin the next year with the round One Hundred Thousand. Will the reader of this supply at least one name towards this result? Every new name received this month will come in for an extra allowance of two months' papers, as noted in another column. The Great Strawberry to be distributed, will, we hope, prove a valuable gift; but aside from these extra inducements, the *Agriculturist* shall be made a treasure to every household—a valuable guide for the Farm, the Garden, and the Household—and a source of pleasure and profit to the Young. O. J.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.
(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 12 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only three cents a quarter, if paid in advance at the office where it is received. All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

STEAM PRESS OF JOHN A. GRAY & GREEN, 16 & 18 JACOB STREET, N. Y.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN,"—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 352.

VOLUME XXII—No. 11.

NEW-YORK, NOVEMBER. 1863.

NEW SERIES—No. 202.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

November with its sounding blasts gives warning of the advancing march of Winter, and the prudent man will heed the signal. Everywhere may be noticed the care with which Nature protects her children. The summer glory of the trees has departed, but the fallen leaves spread thickly about the roots, prepare them to withstand the benumbing frosts; and many a bulb and tender sprig and waiting seed, lie snugly nestled within the folds of the kindly shelter. No woven blanket could better protect the pastures and meadows, than does the downy mat formed of the withered blades of grass. Here, too, are safely kept the myriad seeds of flowers that will gladden the fields when Spring shall waken them to life. Nor are the countless tribes of animated creatures forgotten. Warned by unerring instinct, the bee has filled its cells with abundant stores, and fears neither cold nor famine; flies and their congeners have sought sheltering crevices; many insects have burrowed in the earth, and for others, a special form of life has been devised, and their chrysalides hang from fence and bush; the squirrels are gathering nuts and acorns with which to regale themselves in the intervals of their long winter nap; in the wilder regions the bear is looking out his hollow tree, and each animal is rejoicing in the thickened coat which shall shield him from coming storms. Let the husbandman note these kindly provisions, and be equally provident for the creatures entrusted to his care. There may be danger that some domestic animals will be injured by excess of kindness. They should be protected, but not pampered. A horse confined in a close shelter, kept warmly blanketed, fed with unsparing hand, and but little exercised, will be liable to inflammatory diseases from

every slight exposure. Sheep huddled together in warm pens, kept inactive and supplied with abundant food, will be enfeebled themselves, and in the case of breeding ewes, their progeny will also suffer. As with human beings, the first requisite for withstanding severity of weather is robust health and vigor of constitution. With these and plenty of food, animals entirely unsheltered will successfully resist almost any inclemency of the season. But it is both humane and economical to give that amount of shelter which will not interfere with hardiness. A creature exposed to the full force of a winter nor'wester, will shiver off a surprising amount of fodder, and usually of fat also. The importance of this leads us to repeat what we have often said in the *American Agriculturist*, that a large part of the food consumed is used up in the system, actually burned, to furnish animal heat. The need of this repetition is seen in the absence of shelter for stock on hundreds of farms, particularly at the West. We believe it would not be saying too much to assert that the hay and grain annually wasted—burned up for want of protection to animals—would keep twenty-five per cent. more cattle and sheep than are now raised in this country. If any whose animals are unsheltered, are yet doubtful on this point, let them commence experimenting. Build stables or rough sheds for part of the stock, and keep an exact account of the feed consumed by them, in comparison with an equal number allowed to run at large: we have no doubt as to the result. In addition to considerations of profit, there is no little satisfaction in the merciful treatment of dependent creatures. The lowing of unsheltered cows and bleating of neglected sheep are anything but soothing music, while the grateful pleasure which even dumb animals can express in return for proper care, will add not a little to the enjoyments and the attractions of farm life.

Work for the Farm, Household, etc.

Animals.—Keep them always improving. Comfort for the animal is money in the purse of the proprietor. Take them up early for the animals' sake, for the pastures' sake, and for their manure. Provide warm sunny sheds for young cattle, close sheds or boxes for colts, open but warm sheds for sheep, where they can have the range of a dry yard.

Barns and Stables.—A clapboard loose or gone, or a great crack under the door, lets in the cold, and the horse or cow must have more fuel for the fire within the body to counteract the cold from without. Pure air is essential, but let it not come in chilling currents upon man or beast. With ventilators above for the escape of bad air, there will generally be enough good air stealing in almost insensibly through the seams and crevices; if not, admit it from some point where it will not blow di-

rectly upon the animals. Every stable should have one glazed window, and better several.

Butter may be made almost as well at this season as in June, if the feed of the cows is good enough. Sugar-beets and carrots, with plenty of sweet hay and corn-stalks cut up and flavored with bran, corn meal, or cotton seed or other oil-cake with salt as a condiment, will secure the cream which will make yellow butter without annatto, and plenty of it.

Cellars.—The fetid air from decaying vegetables is as bad as the malaria from a swamp; hence be very careful in storing vegetables and in frequently examining those already in the cellar, to remove all roots and leaves beginning to decay. Thorough draining, ventilation, and plenty of lime whitewash, are good, both for the things kept in the cellar, and for those living above it. A little hydraulic lime mortar, with bits of stone and broken glass, are good stoppers for rat-holes. The best cellar temperature is one as low and equable as possible above freezing. In fact a little frost is better for apples than too much warmth. Potatoes endure rather more warmth than apples and other fruits; these must be kept cool, but sweet potatoes will bear quite a high temperature, and should be put in the driest and warmest part of the cellar. Sashes with double glass and an intervening thin space of confined air, are nearly equal to stone walls, in shutting out cold. Protect the exposed walls with a bank of earth outside, or what is neater and better, spent tan-bark, if it be conveniently accessible.

Cisterns.—Pure clean rain water is better for man and beast than well or spring water medicated with lime and other salines dissolved out from the soil. If not already done, empty and clean foul cisterns early, when rains may be depended upon to fill them again. (See note on examining cisterns and wells, elsewhere.)

Corn.—Dampness and frost combined, injure it for food, and especially for seed. Much of the corn brought to this market is sold as "unsound." The sooner it can be husked and placed in dry cribs, the better. The crib should never be more than 3 or 4 feet wide, and let abundant openings be left, by slats at the sides. The eaves should project far over the sides of the corn-house, to prevent storms beating in upon the sides. A rat-terrier dog chained under or in the corn-house, is the best rat-trap.

Corn Husks.—There is a ready sale for this article at about \$10 per ton at the farm in many sections. It is not worth this for fodder, and the difference, if it be cash, will pay for saving them. Torn into fine shreds on a hatchel, they are better than straw to fill beds.

Draining.—There is hardly a farm in America on which some work at surface or under-drains may not be done to advantage this month. So long as the ground is unfrozen, this important

work may be pushed forward. Surface drains should be arranged upon a well-matured system, and protected from washing, by securing a distribution of the surplus water upon grass land, or by stoning the bottoms, or securing a gentle flow of water by greater width. Underdraining the garden will advance spring working a week or two, and make the product much better, by letting in warm air and preventing the chill produced by the evaporation of the water from the surface during Summer. The same results are produced in the field. It pays on almost all soils, even those usually considered dry. Clear the obstructions from the dead-furrow drains in the winter grain. Frost will not kill wheat or rye; frozen water in the soil will. Water in freezing expands one-eighth of its bulk, and tears and heaves the roots; perfectly dry soil does not expand in freezing; and soil merely moist expands but little.

Fuel.—It takes the heat of almost one half of green wood to dry the other half. Therefore keep the Winter's fuel dry and under cover. It will save fuel, time, vexation and health, and be a mercy to the housewife.

Grain usually keeps better in the bin than in the mow or stack, especially where mice abound, while in the bin it is ever ready for market. Do not burn the straw, even in the new rich prairie regions. Let the cattle lie on it. If it can not be used, let it lie even five or ten years; there will in that time surely be some place that will be benefited by an application of well rotted vegetable matter. Clean the grain well for market. A bushel of chaff, foul stuff, or shrunken grain in 100 bushels will lower the price of the whole 3 to 10 cents per bushel—an important difference, and one which will pay well for an extra fanning and screening.

Hedges.—Thorns and other deciduous hedge plants may be set until the ground freezes. Leave evergreens until next May.

Hogs.—They fatten most on the same food when weather is warm. As cold weather comes on, give the hogs warm pens well supplied with dry litter, feed regularly—gradually increasing the amount of food and its richness. Hogs kept in pens will always dung in an out of the way corner, frequently persisting in its being under cover, doubtless for convenience in cold or rainy weather. By watching their habits, and exercising a little *persuasion*, when the pen is first occupied, a great advantage in cleanliness may be secured. For early pigs turn in the males now. Sows run about 4 months (109 to 123 days.)

Horses need clean, well ventilated, and well lighted quarters. They are fastidious in regard to food and drink. The nervous, high-strung nature, which gives the horse his energy, endurance, spirit, and docility, cannot be maintained without constant and judicious care. Young and old horses should be brushed clean or curried daily, blanketed in cold weather, using light woolen blankets in-doors and warm generous ones after exercise and out of doors, especially if exposed, even for a few minutes, to wind, or cold drafts of air. These blankets should cover neck, breast, and flank well. No animal takes so quickly the temper of his master or driver as the horse; so be firm and gentle with him.

Implements on many farms are depreciated more by exposure than by use. Rust is the enemy of iron, and soaking and drying will warp and open, or weaken the firmest wood-work.

Ice Houses.—Ice is becoming year by year more necessary to the comfort, economy, and health of the entire community. During this month prepare ice houses for the reception of the new crop. See that the drainage is good, and that there is no chance for a draft of air, in or out, at the drain. If you have no ice-house, put one up at once if practicable; 10 feet square and 10 feet high, is a good common size. If placed on a side hill, it will save lifting the ice in filling.

Leaves—It will pay to collect all the leaves accessible, for the manure heap, for the hog pen, and for horse and cow stalls. Heretofore they furnish a good fertilizing material; they are also excellent as a mulch.

Manures.—"Your muck is your maun"—manure is money—is an old English farmer's proverb as true as gospel. In England 'muck' is the generic name for every thing of the nature of animal or vegetable manure, or substances in decomposition. (With us it is generally used to denote the black earth found in swamps or low places, and consisting of decayed roots, and vegetable matter.) To secure all valuable qualities in the droppings and urine of animals, and by allowing them to ferment in connection with inert vegetable substances, to convert the whole into the greatest quantity of available plant food, is the great study of the successful farmer. The "muck" of the swamp, straw, swamp hay, and all other vegetable matters easily decomposed, are desirable to use as bedding and absorbents in the stalls, or to mingle with manure in the compost heap. Save every thing of the kind to add to the manure, and use all means necessary, to prevent disadvantageous heating, fire-fanging, etc.

Plowing.—There are few if any soils which are not better plowed in the Fall than in the Spring, for early culture. So long as the ground continues open, keep the plow running. The sod begins to decay, and is quickly decomposed in the Spring. The frosts kill the weeds, and also affect the inorganic part of the soil, causing it readily to dissolve; and more than all other benefits are the getting ahead with spring work, securing dryness of the soil, and ability to plant much earlier.

Potatoes.—Warmth with moisture is injurious, next to actual freezing. Dryness, and a cool but not freezing atmosphere, in the cellar or earth-covered heap, are essentials. When in out-door heaps, dig a deep trench around them with an outlet, so as to keep the bottom of the heap always dry. Add more earth to the heap only as needed by the increasing cold, always patting down each layer of earth smoothly, to shed rain.

Poultry well cared for, pay by the eggs and manure produced. The secret of having eggs all the Winter is, to give the hens the advantages of Summer, viz.: warmth, shelter, light, water, and some animal food to supply the absence of insects which they gather in Summer, with lime enough to make egg shells. They devour and grind up the weed seeds among the grain tailings fed to them; they eat almost every kind of grain. Bones pounded fine, and scraps of fresh meat they devour greedily and convert them into eggs. We find that a cake of scraps from the fat boiling establishments, placed where the hens can pick at it, always keeps the egg machine in operation; if the supply runs out, the eggs are missing.

Pumpkins.—Avoid bruises in handling; store in a cool dry place, always free from frost; remove seeds when fed; dry as directed last month.

Sheep are fast taking the position in American agriculture, which they should. The high price of both wool and mutton is effecting this. The sheep owner or breeder should be a true lover of sheep and watch them carefully, see personally to their wants, anticipate their needs, know them all individually. Thus he will mark the deficiencies of ewes, in form, in wool production, in fattening ability, in breeding qualities, and so match them that their faults will be corrected in their progeny; or he will from the outset devote certain ewes, or their lambs to the butcher, and by thus weeding out his flock, keep it ever improving. Select such bucks as will correct defects, and sort the ewes accordingly into several flocks. Provide secure protection against storms, but give all breeds some range in open yards. April lambs must be spoken for this month. See p. 334. on fattening.

Roots.—A good root cellar is one of the indispensables of good farming. It is one-sided farming into which an extensive use of roots for stock food does not enter, and much of the farming of the United States is very one-sided. Before storing, roots should be clean and dry. Store them so that the turnips may first be used, the sugar beets, mangels and rutabagas subsequently—carrots being used through the stabling season as a pleasant touce

and appetizer for horses, and for milch-cows, mixed with other roots, or cut up and fed by themselves.

Turnips.—It is best to let them stay in the ground until the tops are decidedly frosted, but not so long as to endanger the freezing of the root. They keep longer and wilt less, placed in heaps, strawed and covered with earth, than in any but a very good root-cellar. However stored, have them first dry and free from soil.

Weeds.—Gather weeds into windrows and burn them; do not move far, nor so as to scatter the seeds.

Winter Grain.—The advantage gained by feeding off a rank growth in the Autumn, is questionable after the near approach of cold weather. The danger is, that some spots will be too much denuded of the winter mulching which the foliage affords.

Orchard and Nursery.

Last month's remarks regarding work here, apply with equal force this month. In order to have a good orchard, the work must begin with care and conscientiousness on the part of the nurseryman, and be continued with equal care on the part of the purchaser and planter. The best trees from the best nursery may easily be ruined and rendered valueless, by bad treatment from those who buy them, while, on the other hand, no after care will make a good vigorous tree of one which has been maltreated in its early growth. Careful selection of the trees, and an equal care in planting them, are among the main essentials in starting an orchard.

Cider.—Use clean sound fruit, and see that every part of the process is conducted in a neat manner. Much more fruit is frequently stored than can be used or sold, and this excess may often be profitably converted into cider or vinegar.

Cions may be cut at any time after vegetation ceases if they are kept carefully buried until Spring.

Cellars where fruit is stored should be kept open as long as they can be without freezing. When closed for the Winter, provide for ventilation.

Fruit.—Apples which may have fallen or been bruised in picking, should be marketed as unsound fruit or made into cider, or fed to stock, or they may be dried, as noted on page 341. Hand-picked apples should be placed in barrels and kept as cool as possible without being touched by frost. Toward the close of the month, after they have undergone what is termed sweating, sort them thoroughly and head up the barrels, handling with care; one bruise rots the apple, and the disease spreads rapidly to others. Apples packed in dry oats, leaves, bran, or cut straw, and kept cool, will remain fresh and sound long after their usual time of decay. Some kinds of winter pears bear the same treatment, but it is usually better to keep these upon shelves, not touching each other, and covered with paper. The change of color indicating the ripeness of each one may be readily observed; or each pear may be handled.

Insects are now in their dormant state of larva, or their eggs, containing germs of future trouble, are upon the twigs or bark. Cocoons and collections of eggs are now more readily seen as the trees are naked. Destroy them as soon as discovered.

Label everything in the nursery or orchard according to some plan. If labels are used upon the trees, see that they are of a permanent kind, and at the same time not likely to do injury. If, as is preferable, the record is kept by a map, see that every change or new planting is promptly recorded. The value of a fruit is doubled by having the correct name for it.

Manuring should be done in the orchard. Fruit-trees repay good feeding. Use a liberal dressing of old manure or compost.

Mice.—Young trees will need protection where these are troublesome. Wrappings of paper, tarred cloth, sheet-lead, and various other appliances, have been suggested from time to time. We have not tried any of these, but have found the hard tramping of the snow around the trees effectual.

Nursery Rows.—Plow between them and turn the furrows toward the trees.

Seedlings of nursery stocks, intended for root-grafting, should be taken up this month and stored in the cellar to be worked during the Winter.

Seeds of apples, pears, etc., and stones of peaches, etc., may be planted as directed last month.

Seed Beds.—Seedlings, especially those of evergreens, need some protection the first year. Sift some dry sandy earth over them, and cover them with leaves or cedar boughs.

Kitchen Garden.

There will be plenty of work in a well managed garden until freezing weather stops all operations. The crops still remaining out are to be harvested, and the ground everywhere to be cleaned up, so that every available portion of refuse shall go either directly to the compost heap, or to the pig sty, or cattle yard. All work of preparation done now, will greatly facilitate labor next Spring. In stiff soil it will pay to throw the ground up in ridges with plow or spade, and leave it thus to the mellowing influences of the frost. The details of operations are the same as those given last month.

Asparagus.—Cover with coarse manure. Make new beds, according to directions given last month. The ground can hardly be made too rich. Manure is the secret of the "Giant Asparagus."

Beets.—The harvesting and storing should be completed before hard frost comes.

Cabbages.—These should be covered for Winter as advised in last month's calendar. Finish putting young plants into cold frames.

Carrots.—Dig and store the remaining crops early in the month.

Celery.—Continue to earth up in dry weather. Harvest before severe weather. Stand it upright on level ground and cover with boards and bank up with earth. Allow no earth to fall between the stalks. Latterly, we have practised putting enough for early winter use into the cellar, covering with earth, and leaving the rest where it grows, well banked over with earth when first struck by killing frost.

Cold Frames.—Prepare for use, and set in them, the cabbage, cauliflower, lettuce plants, etc., requiring winter protection. Cover with glass or shutters during cold nights, but keep open by day as long as the weather will admit. When Winter sets in, cover securely, banking up about the sides, and put straw, leaves, etc., over them to exclude frost. Every mild day, open for a short time.

Drain every wet and heavy spot. The whole garden will be all the better for draining; it can be worked enough earlier in the Spring to make it pay.

Mice.—Let no rubbish be left to harbor them. Guard against their intrusion into the cold frames. Dishes of meal, poisoned with arsenic, will soon dispose of them.

Onions.—Cover with litter to protect those sown late to be left in the ground during the Winter.

Parsnips and Salsify are improved by leaving in the ground until Spring. Dig enough for use during Winter, and cover with earth in the cellar.

Poles, stakes, frames, etc., should all be carefully gathered, and housed for future use.

Rhubarb.—Set roots with crowns, any time before the ground closes. Cover with coarse stable manure, to protect the roots and enrich the soil.

Spinach.—Hoe and thin the plants, and cover with straw or other litter.

Turnips.—Gather before injured by frost, and store for household use, and for feeding to stock.

Fruit Garden.

If the weather continues mild, hardy plants may be put out with advantage. We some time ago gave our reason for preferring to have a separate garden for small fruits, rather than mix up fruit and vegetables in the same ground. Whenever sufficient land is at command, it is altogether better for both, to have them separate. Now is a

good season to lay out such a garden, drain and prepare the soil, making all ready for Spring.

Blackberries may be set as directed last month.

Currants and Gooseberries.—Be sure to provide for a good stock of these. Currants particularly, seldom fail. Set out rooted plants, or start cuttings. Ample directions are given in the last and present numbers. Manure old beds.

Dwarf Trees.—Apples and Pears may be set out this Fall. In selecting varieties it is well to heed the advice given by 'Connecticut' on another page. Buy only of parties of known reliability, and be willing to pay a little more for a thrifty well grown tree, rather than take an inferior one because cheap.

Grape Vines.—If you have not already a vine, plant one—or rather several. We have now so many good sorts, that every one can find a grape that will suit even the most unfavorable climate. Planting may be done now. Set out one or two year old well rooted plants in soil deeply spaded and well enriched, and in a locality where water does not stand. Prune this month and lay down the vines. Read article on page 340. Yearling vines, cut back at this season may be protected by having a mound of earth drawn up around them.

Raspberries.—Bend down the canes and cover slightly with earth. New roots may still be set out.

Strawberries.—Give their winter protection to both old and new beds. Straw, spent tan bark, or forest leaves may be used.

Flower Garden and Lawn.

The Chrysanthemums have the garden all to themselves at this time, save here and there a straggling flower that has escaped the first frost; glorious flowers they are to help us prolong the season of bloom into Winter. We look upon the desolation which frost has made in our borders, and sigh for the favorites of Summer, as we remember the tender care with which we cherished them. The memory of the pleasure their beauty gave us should incite us to prepare for their return. We do not wish the readers of the *Agriculturist* to be of that class who have a fever for gardening every Spring, but which subsides, as soon as the novelty and excitement are over. We would have them look upon gardening as a pleasure which is best enjoyed when its labors are distributed throughout the year. To work and plan for future results, is a moral lesson, which can be learned even in the smallest flower garden. During this month, much can be done in preparing for next season's enjoyment. Care for the things we already have, acquiring additions to our stock, and laying out new grounds, or changing old ones, to better suit our improved taste, will give abundant work for November.

Bulbs.—Some are to come out of the ground and others are to go into it. Gladioliuses, Tigridias, Amaryllis, Habranthus, etc., should be lifted before the ground freezes. Let them dry off in the sun, and store them away in a cool place, secure from frost and mice. The Dutch Bulbs, such as Hyacinths, Tulips, Crocuses, etc., should have been planted last month, but better now than not at all. These flowers are great ornaments to the garden in Spring, and produce the best effects in masses. The soil should be light and rich, and if disposed to be wet, drainage is to be secured by removing the soil to the depth of 15 inches and putting in a layer of 2 inches of small stones, brick rubbish or the like; put a layer of good soil over this, working in a plenty of old manure. The bed should be 3 or 4 inches above the general level, to allow for settling. In putting out the bulbs, Hyacinths should be set about 9 inches apart, Crocuses 3 inches, and Tulips 6 inches. Hyacinths produce a fine effect when planted in a circular or oval bed, in rows of distinct colors, one within another. The tops of the large bulbs ought to be 3 inches below the surface. After planting, cover with a good coating of coarse litter manure. The bulbs are to be had at moderate prices at the city seed and florist's stores.

Climbers.—All the tender ones are to be removed from the trellises and protected by a slight covering of earth. The Wistaria will not flourish in many northern localities without this care.

Chrysanthemums.—Keep neatly tied up, and when the frost has destroyed the flowers, the roots may be taken up, divided, and re-set.

Dahlias.—Lift the roots on a fine day, before freezing weather. Care should be taken not to break the roots from the stem. Be sure to have them correctly labeled before they are put away. Dry the roots for a few hours in the sun, and store away in a cool vegetable cellar, under the stage of the green house, or in boxes, or barrels of dry sand, in any place where they will not freeze.

Hedges of deciduous shrubs may be set now. Hedges of dwarf pears are highly recommended by friends who have tried them. The young trees are set two feet apart and grown like any other hedge; they fruit very well treated in this way. Such a hedge would be an appropriate boundary between a fruit and flower garden.

Frames and Pits.—The plants in these should have air every fine day and be carefully covered at night. If mice trouble them, set poison or traps.

Lawns.—Rake off the fallen leaves. These will be needed for protecting plants in the borders, or as additions to the compost heap. Give a good top-dressing of fine compost, and roll if necessary.

Perennials.—Phloxes, Dicentra, and others, may be divided and replanted.

Roses.—The tender varieties may be potted and placed in a pit, or cool part of the green house, or be wintered in the cellar. The climbing sorts do better if laid upon the ground during Winter.

Protect all tender things. Even hardy herbaceous plants will come out all the better in the Spring, if a few forkfuls of manure are put over their roots. The broadleaved evergreens, such as Kalmias, Rhododendrons, Holly-leaved Barberry, etc., need some shelter. Cedar boughs stuck in among them, or a rough thatch of boughs made over them, seem to answer better than tying up in straw. Where evergreen boughs cannot be had, a screen can be made with sticks, and a few bundles of straw. This is not needed so much as a protection from the cold of Winter, as to shield them from the changes of temperature in Spring. Even with the Rhododendron some care of this kind will repay all the trouble it costs.

Shrubs and Ornamental Trees.—Hardy sorts may be planted now, taking plenty of time to do it well.

Green and Hot-Houses.

In this country any glass house for plants is popularly called a green or hot house, without making any distinction between the two. Strictly speaking, a green-house is a building intended to preserve tender plants from the effects of frost, and without any regard to growing them. The temperature is kept low—from 35° to 45°. In the hot-house plants are to grow and flower, and the temperature ranges from 60° to 75°, or even higher, according to the character of the plants it contains. Some houses are constructed with a partition, and the heating apparatus so arranged that the advantages of both a green and hot house can be combined under one roof. Of course directions for management can be given only in the most general terms, as each house will require a treatment corresponding with the end to be accomplished.

Where the green-house is used merely for storing plants, the care required is but little. Having put the house properly in order, and stored it with those plants needing winter protection, or which are only to be forced at a future time, attend particularly to ventilation, as the change from out-door air to a confined room should not be suddenly made. During rains, fogs, and frosty weather, the doors and windows should be closed, and before the end of the month some fire heat will be beneficial. Little water will be needed, and but little care in other respects; the

plants may be left to a quiet rest. The decayed leaves should be picked off as they appear, and everything be kept neat. A good stock of bulbs should be potted to be taken to the forcing house at intervals for a winter bloom. The green-house is also the appropriate place for keeping a supply of the various plants to be taken to warmer apartments for flowering during the Winter.

The hot-house should be attractive even thus early in the season, as many of the blooming plants have not ceased to flower since their removal from the borders, and others are coming into bloom. A nearly uniform heat should be maintained, ranging from 55° to 65°, or even 70° in some collections. One of the first things requiring attention, is to have a full stock of young thrifty plants put in a growing condition, to furnish a succession of bloom during the entire Winter.

Bulbs should be brought from cooler apartments only as they are wanted to bloom.

Caneelias are beginning to push out anew, and some of the flower-buds are well swollen. Syringe and water more freely, giving them light and air.

Fires will need careful attention, as a little neglect often causes much mischief. Most of the plants being tender, a near approach to the freezing point will check their growth, while too much heat will unduly force them.

Grapes.—Prune and lay down, or tie up vines which have ripened their wood. Give them a season of rest now. If the roots are in an outside border, cover them with manure, straw, etc.

Insects.—Keep them in check at the beginning, or they will increase rapidly. Hand-picking, syringing, and tobacco fumes, are appropriate antidotes.

Pots, tubs, and boxes, containing growing plants, should be frequently examined. Keep the drainage open, remove weeds and moss, loosen the soil, and add liquid manure or rich earth to those plants which are flagging. Prune or pinch to a good form, and have them all arranged in a convenient handsome order, the lower growing varieties in front.

Soil for potting should be liberally provided for immediate and future use, it improves by keeping.

Verbenas, Pelargoniums, Petunias, Salvias, and other bedding plants, should be started from cuttings to provide a supply for winter flowering, and for planting out in the Spring.

Water.—Give moderately, more to rapid-growing plants than to those which are resting. Syringe the floors and walls frequently, to induce evaporation.

Apiary in November.

Prepared by M. Quinby—By Request.

The apiarian who has attended to his work at the right time, and has everything now in the right place, will find but little to do among the bees this month. Hives may be painted at this season without seriously injuring the bees in them. If not satisfied with the condition of the winter stocks, examine them again on a cool day; many things may be now ascertained which were difficult to observe in warmer weather. Kill the bees of very small colonies even now. It is almost impossible to get them through the Winter, and most of the honey, if they leave any, will not be fit for the table.

Any one having the movable combs can make the straw hive available the coming winter. Make the inside of the same dimensions as the wood hive. As soon as ready, any time this month or next, transfer bees, combs, and honey, to the straw hive. To the hive described on page 301 of the *Agriculturist*, there should be added during cold weather, a mat for the top, made nearly like one of the sides. In the "leaf" hive, the frames are not attached to the sides or top. For this, a square box, or basket of straw instead of the wooden box, can be made, to set over the frames for the Winter. Straw hives made in this way, are much superior to the conical style, for wintering the bees, especially if used only for Winter and Spring.

The number of patent hives, instead of diminishing, is increasing yearly. Not one in a hundred possesses any real merit over the old box style. The readers of the *Agriculturist* should be guarded against humbugs in bee hives, as in other matters.

At this season the venders will be around, and if they can ascribe no other merit to their hive, than the fabulous quantity of honey stored, because the bees could work best in their hive, it will be safe to let them pass. If the story of a large yield is true, these peddlers are generally so ignorant in the matter, as not to know it is owing to the colony, pasturage, feeding, robbing, etc. Every body having experience knows that with a suitable cavity for deposit, bees will store as much honey in one place as in another, whether flour barrel, nail keg, or square box. A hive for improved bee culture is not expected to increase the amount of honey, but to facilitate the division of it—so that we can take a portion of it, leaving the rest for the bees—and to render easier the inspection of the interior. Aside from the movable comb hives, it is difficult to find an improvement over the old box, with the surplus boxes added. One not sufficiently acquainted with the nature of bees to take advantage of some of the facilities offered by the movable combs, would do better to use the simple box, until he has acquired the requisite practical knowledge to make the others profitable.

Pumpkins, Squashes, and Gourds.

The **Second Annual Exhibition** of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS, at the office of the *American Agriculturist*, 41 Park Row, New York City, opens on Wednesday, Nov. 4th, 1863, and the following Prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

A—For the Heaviest Pumpkin or Squash.....	\$10.00
B—For the 2nd Heaviest Pumpkin or Squash....	5.00
C—For the 3d Heaviest Pumpkin or Squash....	3.00
D—For the Best Pumpkin or Squash for cooking.	5.00
E—For 2nd Best Pumpkin or Squash for cooking	3.00
F—For the largest yield on a single Vine.....	10.00
G—For the 2nd largest yield on a single Vine....	5.00
H—For the largest and finest collection of Fancy or Ornamental Gourds*.....	7.00
I—For the 2nd largest and finest collection of Fancy or Ornamental Gourds*.....	4.00

*All to be grown by one person and to be accompanied by positive evidence from the grower, and one disinterested person who assists in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at auction, or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 15th, and deliver specimens for competition on or before Nov. 2d. Specimens to be delivered free of charge.

Note 3.—The same specimen can compete for only one of the premiums offered above.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

A Full Basket.—In these pages we present a large number of items, many of which are too important to be overlooked, merely because they are in smaller type.—We have many letters still unanswered. Many who do not find a special reply to their queries will find their answer in some of the more extended articles, or in the Calendar. The great majority of our queries concerning grape vines, for instance, are satisfied in the article on page 340, and so with other articles. We can safely say that the short items given on these pages require more varied information to write them, and more care in preparing them, than the rest of the paper. Questions are often received which we can not answer, nor can any one. New questions occur which can only be settled by actual experience. Asking questions is vastly easier than answering them. There is now on file a letter containing fourteen distinct queries; these cost the writer but little trouble, but it will take a great deal of thought to answer some of them. We do not speak of this with a view to discourage questions, for we like to have them, but to excuse ourselves to those who may think that they are neglected.

Sending the Premium Grape-Vines.

Premium Vines which were secured last Summer, will be sent out the first week in November. The Concord will be marked by a string tied around each, inside of the oil-cloth; all the others will be Delawares. Unpack

them carefully when received, and slightly bury them, root and stem, in moist soil for a day or two, and then, if to be left long before transplanting, uncover the stem portion. Set out in a dry soil, preparing a deep wide border or bed, with plenty of rotten manure if the soil be not already good. Rotten sods, muck, or black surface soil, make a very good bed. When the ground begins to freeze hard, cover the vines lightly with litter or straw, to prevent alternate thawing and freezing. Too much straw may harbor mice. The vines have had two seasons of growth, and are well rooted. The smallness of the Delaware vines may disappoint some who do not know how weak a growth this variety always makes for the first two or three years. Our vines are fully as good as those of similar age usually sent from nurseries.

Paper Mill Waste.—“R.” of Chester

Co., Pa., writes to the *Agriculturist*: “Near my place is a paper mill, from which runs a large quantity of stuff containing soda, lime, ink of old papers, and dirt of the rags. By digging a hole in the ground and turning the wash in, I can obtain it all. Now if I haul weeds, dirt and such stuff, and turn this wash on it and thus compost it, will it be of use to the land?”.... There is likewise a large quantity of “bleach” (chloride of lime) thrown out into the race which I can get. “Will it benefit the mixture?” To the former query we answer, *yes*; to the latter, *probably*.

The Expected Crop Reports from

the Agricultural Bureau have not come to hand, at the early date we are obliged to go to press in order to work off our large edition in season. To be of any special value, however, the reports for September should certainly have been ready for the public earlier than Oct. 19th. There is a widespread and growing feeling, that we need at the head of the Agricultural Bureau a man who is more efficient, and less of a politician. There are good men in the subordinate positions—Saunders, Glover, Grinnell, &c.—but what can these avail, if the head be defective. We had hoped for better results than any they yet manifested. Of this more, when Congress meets.

Emigration to Delaware.—G. W. Fortune, Ashtabula Co., O.

There is on foot an organized plan for encouraging emigration to the State of Delaware. The Circular of the Association formed for this object, states its purpose to be “the improvement of the State by the introduction of agriculturists, artisans, manufacturers, and tradesmen from other States. It is proposed to accomplish this by giving information concerning the desirableness of the State as a place of settlement, and by employing agencies to form companies of colonists, and facilitate them in their immigration and location.” Governor William Cannon, as President, heads the list of officers. The movement appears worthy of attention from those desirous of changing their location, but our advice in all such cases is for each one to personally visit and minutely inspect any locality, before taking any steps toward settling in it.

An Aged Lady's Investment.—There

resides at Elizabeth, N. J., a lady in her 95th year, who was therefore 18 years old at the close of the Revolutionary War. She speaks like a true patriot of the stirring scenes when the foundation of the Republic was laid, of the Government whose whole existence she has witnessed, and of passing events. She has had some money at interest in bonds and mortgages, but recently transferred it to the U. S. bonds, expressing her desire to aid the Government all in her power. Fortunately, she and many others can now serve both their own and their country's interests by investing in these bonds, for we know of no better-paying good security. Those who took these bonds early in the year, will, the first of this month, receive interest at the rate of 6 per cent. in gold, which at the present premium is equal to nearly 9 per cent. interest. Some interesting information on this topic will be found in the circular on page 348.

Sunday-School Question-Book, No.

2.—The great number of persons who have used the little book called “Lessons for Every Sunday in the Year,” will be pleased to learn that “Series No. 2” is to be issued during this month. This new book is on the same general plan as No. 1, and is designed to follow it, though it may be used independently. It has received a great amount of labor, and is very complete. We feel quite sure it will be esteemed the best Sunday-School book ever issued. It embraces the whole New Testament, and contains a very great amount of matter condensed into a small compass, and yet in so plain and simple a manner as to be adapted to small children as well as to older scholars. The price (10 cents, or 14 cents if sent by mail) is the same as the first series, and will barely cover its cost. Persons sending for either book should be careful to state whether No. 1 or No. 2 is desired. See last column on page 347 of this paper.

Ought Stable Floors to Slope to the Rear?—Floors thus sloping allow the urine to flow off away from the animals, hence they are so constructed. Geo. P. Bissell, King Co., Wash. Ter., protests against this practice, and presents forcible reasons. He says: "No sound animal seeking rest takes a position with the fore-feet higher than the hind, but rather the reverse. The philosophy of it is, that the fore-legs (of neat cattle and horses) are straight and calculated to support the greater weight (without muscular effort). Suppose the horse to be in motion, then every one can see the hind-legs to be instruments of progression, and that the fore-legs do little more than catch the rebound, and sustain the weight of the body. Do urge it upon the whole world to cease torturing their animals by forcing them to stand with their weight thrown upon their hind-legs."—Mr. Bissell constructs his stable floor of slats, with spaces between them sufficient to let at least all the liquid excrements fall through, while the rear of the stall is $\frac{1}{4}$ to $\frac{1}{2}$ inch higher than the front.

Tight Mangers Objectionable.—G. A. Jening, Henry Co., thinks that tight mangers may be injurious to the health of horses, as they are required to feed with their noses thrust into the hay or other fodder, and are thus excluded from fresh air, and dust is drawn into the lungs. He proposes a manger made of strips two inches apart, with a frame work follower to rest upon the hay, the latter to have interstices large enough for the horse to readily draw out the hay. This may be somewhat of an improvement, though we do not apprehend injurious results from the use of the box manger.

Scalding Hen Lice.—"H. P." writes to the *American Agriculturist* from Marietta, O., that his poultry house was swarming with lice, which covered the nests, roosts, floor and sides. As an experiment he gave the whole apartment a good drenching with hot water from a sprinkler, repeating it three times, and the vermin have disappeared. They will probably appear again soon, unless the hens also are cleansed. Give them ashes mixed with sulphur in which to dust themselves.

What is the Matter with the Potatoes?—"Workman," has left with us some potatoes of the Prince Albert variety, in which the tubers are studded all over with small potatoes from the size of a small pea to that of a pullet's egg, and asks the cause of this growth. We suppose that on account of the drouth the first formed tubers stopped growing and ripened. Favorable weather following the ripening of the first, a new growth started, and the eyes which would, if planted in Spring produce stems, now develop small tubers. This difficulty being due to a peculiarity of the season, we can suggest no remedy. Gardeners sometimes produce new potatoes in a manner somewhat similar to this second growth of tubers, by keeping potatoes in a cool place through the Summer, retarding vegetation as much as possible, and picking off whatever sprouts appear. In Autumn these potatoes are packed in boxes alternately with layers of light soil 5 or 6 inches in thickness, and kept in a cellar or other place where the temperature is about 60°. In three months they get a crop of small potatoes which are produced at the expense of the large ones, and without any growth of vines.

Farmers' Clubs—How to Organize One.—"G. P." Athens Co., O. The simpler the organization the more effective. Every member should be able to carry the constitution and by-laws in his head. In case a library is wanted, or any special business is to be conducted, tools owned, or work done by the club, special regulations will be required; but when it is only desired to hold meetings for discussion of agricultural subjects, to exchange ideas and seeds, and have a good social time once a week or fortnight, you will need only a Chairman, to be elected at one meeting to preside at the next, a Secretary and Treasurer perhaps, to be elected for the season. These, with one or two other active men, should constitute the executive committee, and manage the affairs of the club, make some simple rules, appoint meetings, and in short, do every thing which the club does not itself do, all their doings which affect future interests of the club being subject to its approval. The principal responsibility will devolve upon the Secretary, or the Chairman of the Executive Committee, who should be the recognized business man of the club. Clubs which have any other constitution than an understanding to behave like gentlemen, usually neglect it.

Corrosive Sublimate for Trees.—Milton Painter, Balt. Co., Md., writes to the *Agriculturist* that, having an English elm badly injured by insects upon its foliage, he bored a small hole nearly through the body of the tree, filled it with powdered corrosive subli-

mate, and stopped up the hole with wax. This was done six or seven years ago, and the leaves have been nearly untouched until the present time. The same was tried upon small locust trees, and it caused the borers to back out in less than 48 hours, and they have not since troubled the trees. He proposes to try the same treatment for the cure of "black knot." Notwithstanding the testimony of Mr. P., we are quite skeptical upon the subject of medicating trees, and are disposed to attribute his apparent success to causes not connected with the treatment. We should be glad if it were proven beyond doubt that a poison could be introduced into the circulation of a plant in sufficient quantity to render it free from the attacks of insects, and not injure the tree. We do not assert that it cannot be done, but much doubt it. If any other friends have trees upon which they are willing to risk the experiment, we should like to have them try it and report the results. There are plenty of locust, and plum-trees also, fit for no other purpose.

Maiden's Blush Apples.—We have received, through the kindness of N. Farnum and Solon Robinson, a box of apples from the nursery of James Smith, of Des Moines, Iowa. The fruit was all fine, but the specimens of Maiden's Blush were remarkable for their beauty. Nothing more perfect in surface, form, and color, can be imagined than one specimen of this, which is still upon our exhibition table. It is so wax-like in appearance that not only people in general, but distinguished pomologists have doubted, from merely looking at it, that it was a natural fruit. We have had waxen fruit mistaken for the natural, but never before had a real fruit which people insisted upon calling artificial. The deception, if such it can be called, was so perfect that we were obliged to label the apple "not wax." The tree is a good bearer, and the fruit of fair quality for table, cooking or drying.

The Apple Pie Melon.—Mrs. G. P. Cook, Saratoga Co., N. Y., writes to the *American Agriculturist* that she considers the apple pie melon a valuable acquisition to the housekeeper. Her method of using it is, to add tartaric acid or pie-plant (rhubarb) to give flavor in making apple or mince pies. For custards, the stewed melon is strained, thinned with milk to the consistence of sweet cream, seasoned as for ordinary custard, and one egg added for each pie.

Value of Names for Fruit.—Fruit always sells better if it has a name. It should, of course, always bear the correct name, great confusion is often caused by ignorant persons who have fruit for sale, giving false or fanciful names to well known and named varieties. No person, except the originator or introducer of a new fruit should ever name any fruit without consultation with recognized pomological authorities, or the concurrence of some well known pomological, horticultural, or agricultural society. The name should only be given after diligent comparison of the fruit with others, and proving so far as possible, that it is distinct. The name first given with a published description of the fruit, holds.

Plants for Names.—From Water-Vliet, Mich. [address lost]. No. 1, is *Lamium maculatum*, or Spotted Dead-nettle, an old and but little cultivated plant, but quite as pretty as some now cultivated for their variegated foliage. No. 2, appears to be the Blue Gilia, *Gilia capitata*, and No. 3, is not in a condition to be made out. Leaves should be sent as well as flowers.... J. M. Lain, Indiana, sends *Cassia Marilandica*, or American Senna. It is one of our most showy plants and is frequently cultivated in gardens. Mr. L. says that under the name of "wild pea" it is used in dyeing a drab color—and asks if it has the tanning principle of sumac. We have not at hand an analysis of the plant, but we doubt if it has sufficient tannin to make it available as a substitute for sumach in tanning leather. It is used medicinally like the imported Senna.... Mrs. Jane Hill, Stark Co., Ill. The plant is probably *Aster multiflorus*; not usually rare.... Harriet, Montrose, Pa. The plant sent is the Long-tubed Centranthus (*Centranthus macrosiphon*). It was sent from this office this Spring in our seed distribution.... Mrs. H. B. Comstock, Cortland Co., N. Y. The "chickweed like plant" is *Anayallis arvensis*, or Pimpernel, and is not rare near the coast. The spotted leaved specimen is *Mertensia Virginica*, noticed in last month's basket. The other specimen is a species of *Euphorbia*, but the seeds are not ripe enough to enable us to determine which.... Mrs. F. G. Stanley, Adams Co., Ill., sends *Spigelia Marilandica*, commonly called Pink Root, though it is not at all related to the common pink. The root is a popular worm medicine. It is worth cultivating for the beauty of its flowers.... R. C. Smith, New-Haven Co., Conn. The plant is *Phallus impudicus*, the Stinking Morel. It is not to be confounded with the eatable Morel, as it is said to be highly poisonous. The plant is a fungus, is most re-

pulsive in appearance, and has a smell worse than a con- gress of dead rats. It springs up where there is decay- ing vegetable matter. Probably a free application of salt would destroy the underground fibres from which the aboveground offensive portion springs. A digging out and removal of the soil for a few feet around the place where it appeared would be pretty sure to exterminate the disagreeable visitor.... A. Heus, Medina Co., Ohio. The plant suspected of poisoning sheep is some kind of an *Eupatorium*, but as you have sent us no leaves, we can not make out the species. It is not likely to be the cause of the trouble.... A. F. Alden, Peoria Co., Ill., sends us *Cuphea viscosissima*, the Clammy Cuphea. With Gray's Manual, the minute observation which has evidently been given to the plant, would certainly have led to the proper name.... Mrs. Wall, Alleghany Co., Penn. We can not determine the plant with any certainty from the leaf sent. It would be guess work. Send flower or fruit.... H. E. Eastgate, Ulster Co., N. Y. The vine is *Chioenes hispida*, the Creeping Snowberry. It is not closely related to the shrub commonly known as Snowberry, but is more nearly allied to the Wintergreen. L. Norton, Onondaga Co., N. Y. The vine is *Clematis Virginiana*, the Virgin's Bower. It belongs to the Ranunculus family, but you probably did not make out because the flowers are often dioecious. It is worth cultivating as a climber, being very pretty in flower and fruit.

Is the Strawberry a Fruit?—A. F. Alden, Peoria Co., Ill. There are many things popularly called fruits which are not such in the strictly botanical sense of the term. The true fruit of the strawberry is the little grains which are distributed over or imbedded in the pulpy portion. Each of these grains is a little one-seeded fruit, and results from the ripened ovary of one of the many pistils found in the blossom. All these pistils are crowded on the flattish portion in the center of the flower, called the receptacle. This, as the ovaries ripen, enlarges, becomes pulpy and fine flavored, and forms what we call the fruit. It will be seen that the strawberry is a fruit or not, accordingly as we use the word in a popular, general way, or in a restricted botanical sense.

Planting Strawberries.—D. F. Marekres, Conn. Fifteen to 18 inches apart, and one plant in the place is near enough. If the runners are pinched off, the plants will form large crowns, and the leaves of adjacent plants will touch one another. Plants forced in the house in the Winter will not fruit again in the Summer.

What Grapes to Plant—200 Vines to Produce Grapes for the N. Y. Market.—At almost all times, and especially since our recent Grape Exhibition, inquiries are addressed to the Editors of the *American Agriculturist*, asking: "What grapes shall I plant." For example, a gentleman says, "I want to put out 200 vines to raise grapes to sell at the most profit in New-York." We advised: 20 *Creveling*, 25 *Hartford Prolific*, 30 *Concord*, 30 *Delaware*, 20 *Union Village*, 10 *Diana*, and 15 *Allen's Hybrid*; and for the following reasons: The *Creveling* is a fair grape, and being one of the earliest, will sell well on this account alone. The *Hartford* is next earliest, very prolific, of fair quality, and will therefore sell well. The *Concord* will yield more pounds than any other, for the same trouble and number of vines, and is also of good quality, so that most people will buy it also. The *Delaware* grows slowly, and does not yield largely at first, but its superior quality will command a good price from a considerable class of persons. The *Union Village* is very large, of fair quality, will sell well for its size alone. The *Diana* is of peculiar flavor, light color, and will suit a particular class of buyers who will pay more for it than for the black grapes. The *Allen's Hybrid* is the most promising hardy white grape we have, is delicious eating; the fruit will sell at a high price.—The above list we submitted to a large meeting of Fruit Growers, and it met with almost unanimous approval. Two or three objected to the *Diana*: with us it does very well. The above list be it noted is for market purposes in New-York, though it is not a bad list for home use, and may answer for other cities north of Washington.

"Rats," "Mice," and "Waterfalls."—Most of our lady readers know that the cushions over which ladies' hair is dressed a la mode, are called "rats," from some fancied resemblance. The names "mice," and "cats," are given to the smaller and larger cushions; while the hair is dressed in fantastic forms called "bows," "waterfalls," "butterflies," etc. A dashing Philadelphia belle, leaving an order for a hair-dresser to attend at her residence, added "Bring two rats, four mice, a cat, and a waterfall."—"Poor young thing," said a smooth haired Quaker matron, who heard the order, "she's lost her mind."

Steamed Fodder—Testimony Wanted.—Will not some of the readers of the *Agriculturist*, who practice steaming fodder for cattle, give their experience. What kind of a boiler is used? Does the waste steam from an engine impart a flavor offensive to stock? What estimate of the net savings can be made?

Butter Dairy.—"E. S. M. H.," of Otsego Co., N. Y., from six cows, made and marketed 1100 lbs. of butter, besides using all that he wanted in his family. This from a dairy herd consisting of 4 old cows, and 2 two-year old heifers. Next year he calculates on making an average of 200 lbs., at least, to each cow.

Milking Machines.—"T. J. B.," of Oregon. No machine has yet been devised which stands the test of use. Few, if any, of the many articles patented for this purpose, are now offered for sale in this country.

Swans in the Central Park.—"S. G. Harvey, Woodford Co., Ky. The swans are a success here, and would be with you. Some of the first importations died, partly from not understanding their habits, and partly owing to improper food given them by visitors. There are now some 25 or 30 of them, sailing majestically upon the lake in the Central Park; they are so tame they will eat out of one's hand.

Leached Ashes.—A Young Farmer in Windsor, Ohio, asks: "How much can one afford to pay for leached ashes and haul them $\frac{1}{2}$ mile for a clayey soil."—Better pay 25 cents per bushel for unleached than 5 cents for leached ashes as a general thing, but after all the leached ashes may be worth to you even the former price. They are often an excellent application to grass land, and a desirable ingredient in composts from which they do not liberate the ammonia. You will have to experiment for yourself, as the effects of leached ashes are very different on different soils. On many parts of Long Island, farmers prefer to pay from 14 to 25 cents per bushel rather than do without them. Hundreds of canal boat loads are brought from the interior and western New-York, and sold here.

Will it Pay to Buy and Haul Manure.—"C. G. M.," Highland Co., Ohio, can get manure by paying 25c. per load, and hauling it to his farm $\frac{1}{2}$ mile—and asks will it pay? Figure it thus: Manure 25 cts.; man and team (going empty 10 minutes, loading 20 minutes, returning loaded, 30 minutes,) 1 hour's work 25 cts.—total cost 50 cents; and then ask yourself if a load of such manure as you can buy will be worth 50 cents on your farm. It probably will be worth at least three times that, if you make a proper use of it.

To Char Saw-dust.—"A. L. B.," of Perry Co., Pa. Saw-dust may be charred in any vessel from which the air can be excluded, and which can be exposed to a strong heat, a gas retort for instance, or an old stove-pipe covered with a coat of clay and sand, having one end stopped tight, and the other only partially closed, to allow the free escape of the gases evolved during the heating.

Refuse (hair and bits of hide) of Tanneries.—Frank, of Louisville, Ky., asks what to do with this refuse, and if he may add lime to it?—Compost it with good soil if you have not peaty muck, grass sods, weeds, straw, etc. It will convert a great bulk of vegetable substances, otherwise not worth much, into good strong manure. Don't let lime or unleached ashes come near it. Apply it to any crop benefited by good stable manure, and after a little practice you can judge of the strength so as to graduate the application according to the needs of the crop and the land.

Brakes in Pastures.—"B.," Providence, R. I., writes that he has succeeded in destroying brakes in land where they rendered several acres useless, by mowing them while they were in full and vigorous growth—once near the end of June, and again in August. After the second year they have mostly disappeared.

Lime—A Chemical Question.—"Why does lime or ashes act as a disinfectant, and yet release the ammonia from manures?" asks "J. R. P." The action of lime on organic matter is much like ley upon the grease and matters mixed with it in soap making. Ammonia being formed only as nitrogenous substances reach the final stage of decomposition, when the lime or ashes is added to any substance in which ammonia exists ready formed, the ammonia escapes, and further decomposition is in a measure checked.

Roots or Corn.—A farmer of Lawrence Co., Pa., asks: "Does the culture of roots pay equal to

that of corn?" and "which is most profitable, rutabagas or beets?" There is no doubt but ordinarily more nutriment may be obtained from an acre in rutabagas or mangel wurtzels, than from an acre of corn. This does not settle the question "which pays best." Corn is a much more concentrated form of food, adapted to different uses; both are excellent, and no stock farmer should neglect either crop. For milch cows, beets (either the French sugar, or the mangel wurzel,) are best; for other stock, rutabagas are equally good, and probably yield a greater amount of nutriment per acre. A variety of roots is always useful; sometimes the fly hurts the turnips while the beets escape; or a blight may attack the beets, and turnips escape injury. Avoid relying on one crop.

Clover Seed Hullers.—Many inquiries have been received at the *Agriculturist* office for information concerning the price of clover seed hullers, where they may be obtained, etc. We usually refer such parties to reliable agricultural warehouses, but it would be money in the pockets of the manufacturers of good machines, and a great saving of time to us, if they would properly advertise articles wanted by the public.

Highly Agricultural.—Among the prizes offered at an Agricultural and Horticultural Society held in one of the Eastern States this year, were two silver cups for the best rifle shooting!—An extra entrance fee of 25 cents was charged for admission to this part of the performances.

Costly Rabbits.—A suit has recently been decided in England awarding \$500 damages to a tenant for injuries to his crops by the landlord's rabbits. They gnawed through the dividing hedge and destroyed the wheat and vetch crop to that amount. The decision is regarded as an important one to those renting lands where the game laws prevent entrapping or shooting game, even on leased premises, except by special license.

Toads in Market.—Live toads form a regular article of commerce in the London Market. They are generally imported from France, and sell for from 50 cents to \$1 50 per dozen, according to size and activity. They are purchased by market gardeners in the vicinity of the city, to protect their choice vegetables from slugs and insects, which they do very effectually.

Weeping Willows not Hardy at the North.—"S. T.," Waldo Co., Me. The weeping willow, when well grown, is a very beautiful drooping tree, but can not be relied upon in your northern climate. It often winter-kills in latitude 42°, on the Atlantic coast.

Elm Trees and other Vegetation.—A subscriber in Boston, Mass., says that he has been advised to cut down his elm trees, as they will destroy all his flowering shrubs, etc.—The Elm makes a dense shade and its abundant surface roots extend to some distance.—Shade is not generally favorable to flowering shrubs, and but one set of roots can well occupy the same soil. Beyond the extent of these influences, the elms can not exercise any prejudicial effect, that we know of.

Fruit from Iowa.—Wesley Redhead, Esq., Pres. of the Des Moines Horticultural Society, brings us some specimens to show that fruit can be grown in Iowa. We certainly never saw finer Rhode-Island Greenings. Lyman Pound Sweet was of very large size, and Bolmar's Washington Plum of excellent quality. Mr. R. informs us that Mr. Smith, one of his neighbors, and the oldest tree cultivator in the vicinity, has about 4000 bushels of apples which will bring him from \$1 50 to \$2 per bushel. The Diana Grape has done well this season, but the Concord is the most successful variety.

Pears for New-York Market.—J. S. Fisher, Niagara Co., N. Y. The Bartlett pear always sells readily in this market, at high prices, if well grown, and received here in good condition. They brought \$12 to \$25 per bbl. the past season. The White Doyenné, (Virgalieu) is a good pear to raise in localities where it does well. It will probably grow fair with you, and is a high priced, well-known pear. There are many other excellent pears, but they have less reputation in this market—the Seckel excepted. The Louise Bonne is not a favorite in this market. Better set mostly standards.

Large Flemish Beauty Pears.—E. W. Hewitt, of Astoria, L. I., placed on our exhibition tables two very fine Flemish Beauty pears, the product of a dwarf tree which bore this season for the first time. They measured one foot in circumference, and weighed 17 and 17½ ounces respectively. The trees were highly manured from the pig pen.

Cranberries in Canada.—A reader of the *Agriculturist* in Tavistock, C. W., asks if cranberries will do well there. They doubtless will—as they thrive in Michigan, and the difference of climate is not great.

Raspberries Killed in Iowa.—Ada Martin, Clark Co., Iowa. You have too tender sorts. The Hudson River Antwerp, and Belle de Fontenay, are probably the best to stand your severe winters. All raspberry canes are better for being covered in Winter. Bend down and cover with a little earth.

When to Set Grape Vines.—J. Camp, Westchester Co., N. Y. Early Fall, soon after the leaves have fallen, is a good time for setting hardy grape vines. The ground is usually sufficiently moist, and the roots will often push out fibres before Winter, and in Spring be ready for an early start. Besides, there is more leisure in Autumn, and the transplanting can be more carefully done.

Fruit Pictures.—Among the many interesting articles on Exhibition at the *Agriculturist* office, special mention should be made of a series of twelve oil paintings representing the fruits ripening during the successive months of the year. They were copied from specimens shown from time to time upon our Exhibition Tables, and are well executed. They were painted by Miss Anne Newberry, of Brooklyn, N. Y., a young lady who gives promise of great excellence in this pleasing department of the fine arts.

White Lilies.—Ada Martin, Clarke Co., Iowa. These are hardy in much colder latitudes than that of N. Y. We have no doubt that they would live without protection; but some litter thrown over the surface ought to make them safe. If you prefer to take them up, do so after the leaves are killed and before the ground freezes, and put them in earth in the cellar.

Plans for Farm Houses.—"W. C. V.," Jefferson Co., Ind., sends to the *Agriculturist* a plan for a one story cottage—good in many of its details, but faulty in others. There are five rooms, and five outside doors, all opening directly into the rooms. There are two porches or small verandahs. One broad piazza or verandah would be preferable and would in Summer be almost like another room. There are only two closets—there should be many. There is no provision for wood-house, wash room, etc. There are three chimneys, two of which are in outside walls. Chimneys should be in inside walls so as to retain the heat in the house. Two outside doors are usually enough for any small house, and they should if possible open into entries or halls in which the stair-cases may be placed, and much room saved. In general, study to have as little outside wall as is compatible with convenience.

Round Flued Chimneys.—"W. C. V.," Jefferson Co., Ind., constructs his chimneys with round flues. Setting a joint of 9 inch stovepipe as a mold, he builds, filling in around it with mortar, brick, or stone, and then drawing up the pipe as the wall progresses.

Salting Beef.—George A. Lowell, Washington Co., Me., inquires for directions for salting beef in the Fall so that it may not spoil by the following June, and yet not have it too salt and hard to be palatable. Will those having successful experience, please communicate their methods for the general benefit.

An Ingenious Swindle.—The Yankees are generally supposed to be the cutest swindlers, but the following shows that some other nations are not far behind. At a show of implements in England there was a trial of steam engines, and one rough little portable machine surprised every one by apparently doing the most work with the least fuel. The fireman was shoveling in only old cinders and ashes, and yet the fire-box was full of flame. At last the secret was discovered. One of the fire tubes had been previously filled with grease, and plugged up with wood. As soon as the plug was consumed, a flood of combustible matter was added to the fire, which kept the engine running long after its due portion of coal had been consumed.

Silk from Utah.—Mr. O. Ursenbach De la Harpe, sends us a fine specimen of raw silk, raised by him at Great Salt Lake City. He thinks that the raising of silk will in time become an important branch of industry in Utah. Next year he proposes to feed a portion of his worms on knot-grass (*Polygonum aviculare*) which he says has been successfully used in Italy. We shall be glad to hear the result.

Fall Sown Fife Wheat.—A. E. B. Hall, Minnesota, requests some reader of the *American Agriculturist* to communicate an account of the results of sowing Fife wheat in the Fall.

Keeping Celery in Open Ground.—M. H. Wetherill gives the following as his plan: A trench is dug about two feet deep, from one to two feet wide, and as long as required. Two boards, one an inch or two wider than the other, are placed lengthwise of the trench, and on the ground, in a position to support the roofing; these are kept in place by pieces tacked on the ends. The roofing is made of boards sawed to a proper length to cover the frame crosswise and project an inch or two over each side. The celery is set up in the trench, commencing to pack at one end and crowding it close together. The boards are then put over, covered first with straw, and then with sufficient earth to prevent freezing. In removing for use, begin at one end, taking off a roof board at a time, and fill up the trench with the straw as the celery is removed.

Japan Melon Seed.—We have several inquiries for this seed, but have no stock from which to supply the demand. It is for sale by Thorburn, by Lane, and, we suppose, by other dealers in seeds.

New Zealand Spinach.—Fine specimens from the garden of Wm. Shaw of Staten Island, were exhibited at the office of the *Agriculturist*. It is quite distinct from the common Spinach, and is regarded as a delicious vegetable. It grows very luxuriantly, its trailing branches spreading over the ground for a distance of 3 feet or more in every direction, and furnishes a supply of fine succulent leaves during the hottest weather.

Large Cucumber.—T. J. Carleton, Hampden Co., Mass., has placed upon our exhibition tables a cucumber—variety not known—13½ inches long, 15 inches in circumference, and which weighs 5 lbs. 3 ounces!

Propagating the Yucca.—G. Wolf Holstein, Lawrence Co., Pa. This is usually propagated by separating the offsets or suckers which are thrown up abundantly. It may also be grown from seed.

The Hermosa Rose.—"M. M. T.," Pendleton, Indiana. All the Bourbon roses flower better for some protection, even the hardier ones. We can not tell how this variety would do in your particular locality. If in doubt, tie it up in straw and bank earth around it, or put it in a pot or tub, and winter it in the cellar.

Evergreens for Shelter.—"H. E. P.," New-Jersey. Red Cedar, Arbor Vita, or Norway Spruce, will each of them make a good shelter to your garden. They will take several years to grow, and a close board fence will give you the needed shelter at once.

A Word from a Laborer.—J. W. John, Woodford Co., Ill., objects to the plan proposed by a writer in our columns, for securing faithfulness in laborers by requiring all seeking employment to produce a certificate of good character from their previous places, before engaging them. He says there are as many dishonest masters as servants, and such an arrangement would give the former an undue advantage. There is undoubtedly some truth in this view, but it would be difficult for a man known to be untrustworthy, to deprive a laborer of his good name by refusing him a certificate; while the possession of such a document is usually beneficial to a person seeking an engagement.

Walnut vs. Oak.—A subscriber in Niagara Co., N. Y., writes: "Black-walnut stumps last longer in the ground than oak. I can not say about posts. I have replaced one of walnut which has stood 17 years."

English Ivy in Illinois.—"Bay," of Madison Co., says that the Ivy will flourish in that State in a northern or, preferably, in a western exposure.

Camellias.—Chas. Edsall, Orange Co., N. Y., asks how to propagate and treat Japonicas. The name of this plant is *Camellia Japonica*, and it is better to call it *Camellia*, as *Japonica* is used as a specific name for many other things, and has no definiteness. It is hardly practicable to propagate them without a green-house. The double sorts are grafted on the quicker-growing single kinds. The stocks are propagated from cuttings, which root very slowly. The plants require a light soil, with a good share of vegetable matter. Peaty earth mixed with sand or earth from sods which have been decomposed, will answer. The great difficulty in the cul-

ture of the *Camellia* in rooms, is the dryness of the atmosphere and the uncertain temperature. They should be in a room where the temperature never falls below 45°, or gets higher than 70°. Occasional washing of the leaves will contribute much to the health of the plant. We have had them flower finely when kept in a room where there was no fire, removing them at night to a warmer room when there appeared to be danger of frost.

G. Wolf Holstein, Lawrence Co., Pa. Camellias can be raised from the seed, but it is a very slow process, and is not to be recommended unless you have plenty of room and a taste for uncertain experiments. You may raise hundreds, and when after some years of waiting they come into flower, there may not be one worth growing.

Vinegar from Apple Pomace.—It is worth remembering that after thorough pressing, the pomace still contains much sugar, which we may extract and make into good and salable vinegar. Wet up the pomace with as much water as it will hold, adding more from time to time until the mass becomes pulpy and well swelled out. Press it and let the extracted liquid ferment. When the alcoholic fermentation has taken place to a considerable extent, the cider may be poured so as to trickle slowly through some pomace mixed with straw and placed in a hoghead with holes in the bottom. This will promote the acetic (vinegar) fermentation, and besides it will add to the strength of the vinegar each time it is poured through the pomace.

Bark Louse—Another Remedy.—Wm. H. Washburn, Maine, writes that he has successfully treated his trees in the following manner: He makes a wash of 4 gallons of water, 3 pints of soft soap, 1 lb. of sulphur, 1 pint of salt, and 3 or 4 lbs. of lime, and enough clay to make the mixture as thick as cream. When vegetation begins to start in the Spring, the trees are thoroughly scraped, and the mixture applied by means of a brush (stirring occasionally), to the trunk and limbs. He says that two years of this treatment have completely freed him from the annoyance.

Silkworms' Eggs.—Will the lady who sent us some eggs last Spring, have the kindness to send us her address, if she will have more to dispose of?

Keeping Cider Sweet.—T. F. Boyd, Orange Co., N. Y., and others. Sulphite (not sulphate) of lime is used to arrest the fermentation of cider or to prevent it altogether. We have no experience in its use. It is sold by druggists with directions.

Michigan Agr'l. College Lands.—We learn from the Hon. Justus Gage, of the State Board of Agriculture of Michigan, that the State has accepted the land grant, and that a Commissioner has been appointed to locate the 240,000 acres donated to that State for Agricultural College purposes.

Salt Meats for Army Use.—The Government has purchased in the city of New York for the use of the army, within the year ending October 31st, 7,349 barrels of mess beef, 42,258 barrels extra mess, in all 49,637 barrels of salt beef. Pork, 86,449 barrels mess, and 87,028 barrels prime mess, in all 173,477 barrels of salt pork—besides, 5,836,258 pounds of side bacon, 1,805,068 pounds of shoulders, and 1,697,277 pounds of hams, making a total of 9,335,603 pounds of cut meats; and of pork in all forms no less than 44,034,003 pounds. These figures are from official sources.

Salting and Packing Pork.—[The following is from one whom we looked up to as a good farmer, at the then West, some thirty-five years ago. His penmanship shows that more than forty, perhaps fifty years of active labor on the farm have not dimmed his eye, nor stiffened his muscles, nor rendered his nerves unsteady.—ED.]—"A subscriber wishes to know through the *Agriculturist* the best method of salting pork." I will tell you my mode, after an experience of 40 years. "Allow the hogs to cool after killing, take out the bows; [ribs and spine] cut off the hams and shoulders; then cut the side pork into strips of convenient width; put a quantity of salt in the bottom of the cask; then put in a course of meat, laying the pieces on the edges; then a covering of salt; then another course of meat, and so on until the cask is full. The whole is carefully kept covered with brine as strong as boiling water and salt will make, skimming the boiling brine so long as anything rises. The brine is put on cold, and I am careful to know that there is always undissolved salt in the barrel. It is not found necessary to scald the brine in Spring. I sometimes use saltpetre, and sometimes not. Hams and shoulders are salted in separate casks. I know of no reliable method of cleansing tainted casks, and would not take a wagon load as a gift, for storing meat."

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed on our tables since our last report:

FRUITS.—Apples: Fine collection from Andre Leroy, Angers, France....Duchess, a fine new seedling; C. H. Rogers, Stormville, N. Y....York Pippins and King; Sulphur Chadwick, West Washington Market, New-York....Gloria Mundi; Richard Weeks, Lakeland, L. I....Roxbury Russet; Mr. Livingston, Fort Lee, N. J....Pompey; E. Williams, Mont Clair, N. J....Gloria Mundi; Mr. Devoc, Morrisania, N. Y....Lynan Pumpkin Sweet and R. I. Greening; Wesley Redhead, Fort des Moines, Iowa....Collection of Crab Apples; E. Frost & Son, Rochester, N. Y....Trumbull's Sweeting and Higby's Sweet; H. K. Hapgood, Warren, O....Alexander, very fine; Daniel Ball, Perry Center, N. Y....Pound Sweet; E. Williams, Mont Clair, N. J....Fine collection presented by Solon Robinson, from James Smith, Des Moines, Iowa....Crab Apples; Ambrose Baldwin, Gerard, Mich., by Solon Robinson....Collection of Apples: S. A. Tabor, Vassalboro, Me....Save-well; Jesse Ryder, Sing Sing, N. Y....Newtown Pippin of 1862; A. P. Cummings, N. Y....Sheep Apple and Apple for name; Mr. Van Brunt, Fort Hamilton, N. Y....Maiden's Blush; J. D. Van Namee, South-st., N. Y....Twenty-oz. Pippin, grown by P. M. Browning, Clitham Four Corners; O. F. Browning....Orange, Baldwin, Hawthornden, Granny Winkle, Chesebore Russet, and specimen for name; E. Williams, Mont Clair, N. J....Pears: Fine Collection of varieties; Andre Leroy, Angers, France....Duchesse d'Angouleme, 19 oz.; C. A. Fuller, 36 Warren-st., New-York....Flemish Beauty, very large; E. W. Hewitt, New-York City....Beurre Clairgeau, Duchesse, Baked fruit, and one for name; E. Williams, Mont Clair, N. J....Striped Virgalieu; Mr. Van Brunt, Fort Hamilton, N. Y....Seckel, 5 oz.; W. Kendall, Cold Spring, N. Y....Seckel, 5½ oz.; Jacques Van Brunt, Fort Hamilton, N. Y....Louise Bonne de Jersey; C. Smith, Morrisania, N. Y....Seedlings; Jas. M. Hannah, Salem, N. J., by Solon Robinson, New-York....Oswego, Beurre Diel, Bezi de Montigny, Urbaniste, Seckel, Alexander, Flemish Beauty, Louis Bonne de Jersey, Ganselles Bergamot; G. Zimmerman, Pine Hill Nurseries, near Buffalo, N. Y....Beurre Bosc and specimen for name; A. A. Leverich, Bowronville, L. I....Fine Duchesse from tree 18 months old; S. R. Trembley, Bergen Point, N. J....Duchesse; Wesley Redhead, Fort des Moines, Iowa....Branch of George IV., very full; Dr. Sanford, Ravenswood, N. Y....Peaches: Seedling; Mr. Howard, Brooklyn, N. Y....Specimen for name; S. R. Howland, Brooklyn, N. Y....Crawford's Late; C. A. Fuller, 36 Warren-st., N. Y....Branch in bearing; S. R. Trembley, Bergen Point, N. J....Seedling from Melocoton, fine; R. B. Dore, 263 West 15th-st., N. Y....Crawford's Late, Melocoton, R. & J. L. Burroughs, Woodville, N. Y....Smock; Sulphur Chadwick, West Washington Market, New-York....Grapes: Diana, Delaware, Isabella, Concord, Clinton, Rolander (foreign grown out of doors); G. Zimmerman, Pine Hill Nurseries, near Buffalo, N. Y....Taylor's Bullitt, Diana, Anna, Concord; E. Williams, Mont Clair, N. J....Hartford Prolific, Isabella, and Catawba; J. A. B. Paradise, Jersey City, N. J....Seedlings; Jas. M. Hannah, Salem, N. J., by Solon Robinson, New York City....Fine cluster; Mr. Dater, Harlem, N. Y....Other Fruits: Apple Quinces; A. A. Leverich, Bowronville, L. I....Belle de Fontenay Raspberries; Moses Baker, Lyon's Farm, N. J....Australian Strawberry Plants in bearing—commenced fruiting June 15th; J. C. Haines, East New-York, L. I....Large Quince, 13 oz.; C. A. Fuller, 36 Warren-st., New-York....Double Musk Melon; John Chambers, Scarsdale, N. Y.

FLOWERS.—Lantanas variety, fine Dahlias; W. and J. Cranstoun, Hoboken, N. J....Night-blooming Cereus; George Stillwagon, Flushing, N. Y....Dahlias; E. L. Walton, Bergen Point, N. J., J. D. Hegeman, N. Y. City, Mr. Tremaine, Hudson City, N. J., and C. S. Pell, N. Y. Orphan Asylum....Balsams and Pancherium; W. & J. Cranstoun, Hoboken, N. J....Tom Thumb Coxcomb; L. Bodenberger, Williams Bridge, N. Y....Named Seedling Verbenas, very fine; Wm. Davison, Florist, Brooklyn, N. Y....Fine show of Cut Flowers; Mr. Kavanagh, Florist, Brooklyn, N. Y....Sunflower 44 inches in circumference; Mr. Miller, N. J....Dahlias and Tuberoses; Charles Hairs, New-York City....Passiflora Decaistne; A. P. Cummings, New-York City....Splen-did Collection of Cut Flowers; Isaac Buchanan, Florist, West 17th-st., New-York....Dahlias; C. T. Crolee, Gardener to James Gordon Bennett, Fort Washington, N. Y....Fine Bouquet; Miss M. A. Cortelyou, Staten Island.

VEGETABLES.—Peach Blow and Bulkley's Seedling Potatoes; E. S. Allen, 102 Chambers-st., New-York....Curious Potato, "Japanese Tommy;" G. M. Usher, Port Richmond, N. Y....New-Zealand Spinach, (*Tetragonia expansa*), Prince Albert Potatoes, very knobby, and fine Lima Beans; Wm. Shaw, Staten Island....Club Gourd, (63 inches long); James Angus, West Farms, N. Y....Chinese Egg Plant; Jacques D. Hegeman, New-York City....Purple Egg Plant, 4½ lbs.; Thos. Davenport, Passaic, N. J....White Flint Corn; J. J. Van Nostrand, Palisades, N. J....Mexican Peppers; Mr. Swain, Bronxville, N. Y....Scarlet-Runner Beans; W. W. Davis, Jersey City, N. J....California Tomato; J. B. Hunter, Tremont, N. Y....Wakefield Sweet Peppers, Egg Plant, Vegetable Marrow, Hybrid Squash, (Cuba and Valparaiso), 147 lbs.; James McCabe, North Orange, N. J....Seed Chinese Potato; G. M. Usher, Port Richmond, N. Y....Prince Albert Potato; Walter Keeler, North Salem, N. Y....Peach-Blow Potatoes; James Lyon, Nyack, N. Y....Purple Egg Plant and Vegetable Eggs; J. L. Miller, Richmond, N. Y....California Tomato, 1 lb. 11 oz.; L. A. Berte, Tremont, N. Y....Club Gourd, W. W. Woodward, Brooklyn, N. Y....Crock-necked Squashes and Orange Beet; Jesse W. Perkins, Gardener to St. Joseph's Hospital, New-York City....Large Radish, 3 lbs.; John Bullock, Bay Ridge, N. Y.

MISCELLANEOUS ARTICLES.—A series of 12 beautiful oil paintings representing fruits in season each month. Miss Anne Newberry, Brooklyn, N. Y....Specimen of Saginaw Salt; Mr. Smith, East Saginaw, Mich....Specimen of Cotton; J. S. Meeker, Piscataway, N. J....Fruit of Osage Orange; Mr. Van Brunt, Fort Hamilton, N. Y....Same weighing 26 oz.; J. B. Tindall, Yonkers, N. Y.

Gold up—Effects upon Farmers.

At the time of this writing (Oct. 14th.) the Wall street bulletins mark gold at 154, and upward, and exchange on London 169½. That is, it takes \$154 of the general Legal Currency of the country to buy one hundred gold coins that were formerly reckoned as dollars, and a little more to buy a draft on London payable in gold dollars or sovereigns. [The peculiar style of reckoning the nominal par of exchange at about 110, or 10 per cent. above the real par, (or \$4.44 to the Pound Sterling,) accounts for the apparent discrepancy between the quotation of gold, and that of exchange. Ten per cent added to 154, makes very nearly 169½. The difference between gold here and in London is generally only ½ to 1 per cent., which pays the cost of shipping it from one place to the other.] Merchandise imported from abroad is paid for in gold, or in Exchange bills drawn against gold, or against flour, grain, meats, lard, tallow, cheese, etc., exported from here.

The effects of a rise in the market value of gold, upon the prices of farm products, are readily seen. Owing to abundant crops abroad, breadstuffs are not now in great demand there. England imports an equivalent to 25,000,000 to 40,000,000 bushels of wheat, even in the best years, buying it where it can be most cheaply obtained—on the European Continent, or in America. This year we have to compete with considerable supplies from the Baltic, the Danube, etc., whence it can be obtained at prices nominally cheaper than here. But the greater relative value of gold, and consequently of Exchange, makes it more profitable to buy breadstuffs and provisions from us. To illustrate: Suppose wheat to be worth \$1.20 per bushel in London. A merchant in New York wishing to pay for a bill of goods in London, amounting to \$6000, can do so with 5,000 bushels of wheat delivered there, or with a bill of exchange, which at 154, (the price of gold), will cost him here, \$9,240 in currency. He could then just as well pay this sum for the 5,000 bushels of wheat (about \$1.85 per bushel,) and send that—or say \$1.65 per bushel, allowing 20 cents extra per bushel for sending it. All that he can save by buying below \$1.65, will be clear profit. If, on the contrary, gold were down to par, he could pay only \$1.00 per bushel for the wheat. The same is the case with all other exportable products—corn, wool, provisions, etc. (The transactions are generally carried on by several parties, thus: The exporter ships his articles and draws bills of exchange against them, payable in 60 days or thereabouts. The foreign exchange dealers buy these bills, less interest and profit, and sell them to the importers who send them over to pay for their goods. There is a mutual system, by which a bill drawn against shipments to Liverpool, for example, can be used in payment for manufacturers' wares in any part of Europe, and even for teas and silks bought in China.)

But the chief fact we desire to illustrate, is, that any advance in the relative value of gold increases the sale of exportable farm products, and sends up the prices. The higher price of these increases the prices of other products. The cost of transporting products from the interior to the seaboard is nearly uniform, so that any advance experienced here, is felt throughout the country. We are not arguing that gold at 154 indicates a healthy financial condition of the country as a whole; we are merely stating that it is specially advantageous to those who raise any kind of farm products to sell. "But"

says the farmer, "the same causes which carry up the prices of my products also increase in the same ratio the cost of what I have to purchase." This is in part true; but it is to be noted that only a small part of the proceeds of his wheat, corn, wool, butter, etc., are used in paying for imported goods of any kind—cloths, silks, etc. Nine out of ten farmers are in debt for land, for stock, for implements, and for store bills. The legal currency they receive for their products, will cancel these debts, dollar for dollar. And right here is the "moral" or practical lesson we are endeavoring to impress upon every farmer who reads the *American Agriculturist*, viz: that now is the time to economize and get out of debt. Money is plenty, and the temptation is to run into extravagance in dress, in furniture, and in living generally. Better use every possible dollar in cancelling old debts. Let the purchase of luxuries or mere conveniences in dress, furniture, etc., be deferred until these things come down to the gold standard—at least if there is a dollar due to any body that will take it now. When Gold is "up," SELL all you can, and BUY the least possible.

Going to the Post Office to Buy a Farm.

Judging from the letters and queries received, there are now more buyers than sellers of farms. It is difficult to answer judiciously, the frequent inquiry, "where shall I locate?" for much depends upon personal circumstances—habits, family, previous experience, etc. A young man, of vigorous constitution, with but a small, healthy family, and his children yet in infancy, may well strike for the cheap lands of the West. There he can grow up with the country. Schools and good society will come in by the time his children are ready for them. With good morals, and good working habits, the chances of success are very favorable. The mid-western States are peopled by well-to-do families whose heads are the enterprising young men and women of the above class, that swarmed from the Eastern hives, fifteen to thirty years ago. They are now the respectable citizens, honored and looked up to—the real "bone and sinew" of the land. Other considerations must decide the question for those more advanced in life, and having larger families. These will be discussed from time to time in the columns of the *American Agriculturist*. Allow us to introduce here an extract in point, from the letter of an old reader, whose long observation of men and things gives weight to his opinions:

"...My friend S., is about to buy a farm. He has fixed upon three localities which appear alike, as respects soil, nearness of market, etc. I tell him that if other things are equal, he must go to the Post Office and let the books there decide the question. The place to settle is where he finds the most letters sent and received, and the most papers taken, especially those treating of the business of the place, for there he will find the most wide-awake enterprising people, those on the lookout for information from every possible source. There he will have the benefit of the example and experience of neighbors who are getting and putting into practice new ideas. There his boys will grow up among intelligent thinking men.... Your books, Mr. Editor, will show that I have been acting upon this idea. I have been constantly drumming it into people. Eight years ago I sent you only one name, then six, then twenty-four, then sixty-five, then ninety-eight, which comprises nearly every family of my acquaintance. I have asked no premium for these names, for I have been more than paid by seeing the awakened spirit of inquiry, the improvements going on, the better culture and management introduced. This has resulted not so much, perhaps, from following any specific instructions of your paper,

as from the indirect hints and suggestions, and the spirit of improvement awakened. I have no doubt that from this cause alone, our farms are worth ten dollars an acre more than they would be, had we had no agricultural paper,—that is, a hundred thousand dollars, on the ten thousand acres owned by your hundred readers here.—I shall keep on doing as I have, and advise every farmer to try to improve himself, his farm and his neighborhood, by acting as self-appointed agent for some reliable agricultural paper—I care not what one, if a good one."

Discussions at the Fruit Growers' Meeting.

The New York Fruit Growers' Society have met regularly every Thursday at 1 P.M., during the month since our last report. We have only space for a brief report of the meeting of Oct. 15, which was large and spirited. After the ordinary routine business of examining and naming, so far as possible, the various fruits on the table, grapes were taken up. The Isabella came in for a large share of malediction. Mr. Field remarked that it never was a suitable out-door grape, and would not ripen unless it received some kind of protection. In some sheltered situations like those of Dr. Underhill on the Hudson, it did tolerably well for a few years. He instanced the attempts of various individuals, who from reports of Dr. U's success, planted from 7 to 15 acres of vineyard with this variety. In no case was it a success.

Solon Robinson was particularly severe on the Isabella. He considered that the introduction of this sort had been a great curse to grape growing, as it nearly always failed to give satisfaction. The reputed success of Dr. Underhill with the Isabella was an injury to the grape growing cause, as it operated to the great discouragement of those who planted this fruit, many of whom in their disappointment turned against the culture of all grapes. Even the grapes sent to market by the Doctor are sour enough to make a pig squeal. They were heralded the country over as superior grapes. This kept up the demand for vines, from the sale of which the Doctor made more money than from the sale of fruit.

Mr. Judd replied, if the Isabella be dead and buried, "say naught but good of the dead;" the Isabella has served a good purpose; without it, during his youth, and early manhood indeed, he would have had no grapes at all. The question now was, "what shall we plant instead?" He recommended a variety ripening in succession. See List in Basket Items, page 325.

Mr. Fuller alluded to the new seedlings already out, and others soon to be offered, and said he should be somewhat cautious of seedlings from the Isabella and Catawba, as already the faults of the parents have developed themselves in the offspring. All the seedlings of the Isabella, and he considered the Adirondac as one of them, were subject to the mildew, which destroys the vitality of the leaf, and then it falls before the fruit is ripened, while the rot of the Catawba develops itself in the Diana, Anna, and other seedlings of the Catawba.

Mr. Carpenter cautioned all against planting Delawares close to a fence, as he had seen the foliage nearly burned up in such situations. He was pleased with the Anna, as out of 15 kinds, this and the Rebecca were the only sorts entirely free from rot.

Mr. Field thinks we should always be cautious about going into the extensive culture of new sorts, as Adirondac, Iona, Israella, etc., which had been tested in but few localities, mainly by those interested in selling plants.

Mr. Pollock, of Morrisania, showed two samples of Native Vines, which were the simple juice of perfectly ripe grapes. He used most of Concord's, a considerable quantity of Catawbas, and a few Isabellas, for he could get but few perfectly ripe berries of the last. The grapes are allowed to remain till over ripe, even till touched by frost; the berries are picked from the stems, mashed in a tub, covered, fermentation allowed till the skins and pulps rise in a mass to the top of the liquid. This is then drawn off, and set to ferment in barrels by itself, while the rest is subjected to pressure, and forms a less valuable sort of wine. The fermentation goes on at the lowest practicable temperature, the air being perfectly excluded. The wine showed, was of 1862 and 1848. The latter was by far the best, and of excellent character, entirely free from anything like foxiness, or the harsh acidity common to the wines of this latitude, from the above named grapes. Mr. P. has about 2,000 vines of various kinds, on a stony side hill trenched 2 feet deep, standing 2½ feet apart each way, trained to stakes, one cane only being allowed to grow. He particularly insisted upon the view that true wine cannot be made, it must grow; that is, it must be the fermented juice of ripe grapes without addition of any kind—in which he is quite right. The Isabella alone will not, in his experience, yield a wine fit to drink. The Concord yields a very good wine, but he prefers a mixture of several kinds,

A MODERN AGRICULTURAL FAIR.

Sketched and Engraved for the American Agriculturist.

Our humorous artist has fairly "taken off" not a few so-called Agricultural Fairs held during this and previous years. Any apparent exaggeration is only due to his reach of vision into the future, where the exact scene will soon be found, if things in this line go on as they have been progressing for a few years past. Time was when an Agricultural Exhibition meant a sampling of the farmer's best productions for the year, with an attendance of men and women who came to learn as well as to enjoy. Some such gatherings we have visited where instruction abounded. High bred cattle and sheep were eloquent in encouragement of enterprise and perseverance in improving farm stock; plethoric swine with melodious gruntings told of careful breeding and well filled troughs; shining samples of grain testified to the benefits of subsoiling and underdraining; and luscious fruits and gorgeous flowers discoursed poetry that all could appreciate. The influence of the scene opened every heart, social feeling had full flow, and all rejoiced in the farmers' festival. It was an evil hour that suggested the introduction of the race-track to increase the attractions of the Agricultural Exhibition. Of the additional numbers brought in, but few were of a class to render the gathering more attractive. The patronage of "horse" men and fast women but poorly repaid for the loss of the respect of the better classes, and there was a speedy falling off, both of attractiveness in the Exhibition, and of the numbers in attendance, and in many societies the annual gatherings have become disgraceful failures. In some cases the managers perceived the drift of the current in time to stay it, and we believe that without exception, where the race-track has been excluded, and proper efforts have been made to promote the legitimate ends of the exhibition, there has been continually increasing prosperity. We may instance the Exhibitions of the New-York State Agricultural Society as compared with those of her sister State, New-Jersey; the former with-

out the races, was a matter of pride to the agricultural community and of gratification to the managers; the latter in spite of the race-track (rather because of it) a failure, which we trust will never be repeated. But further comment is unnecessary: if the facts noted are insufficient to convince the managers of failing associations, of the necessity for a change of policy, we commend the above engraving to their careful study, particularly those in Connecticut who this year actually introduced an ox-race as one of the attractive features.

The New-York State Fair.

We condense the following from the copious notes of one of our editorial associates at this Fair, which opened just as the last number of the *Agriculturist* went to press:—"The exhibition as a whole has been a success, the receipts above expenses, and larger than the previous year.

IMPLEMENTS.—In some departments, the entries were below the average, though lack in quantity was made up in quality. In farm implements and general machinery, there was a creditable display. Plows, harrows, mowers, and reapers, hay spreaders, and elevators, separators, patent bee-hives, pumps, well-curbes, and various machinery for raising water, churns and cheese-vats, abounded in numerous varieties, each better than the other! The steam plow was not on hand. The horse hay-spreader, resembling somewhat a mammoth grass-hopper, attracted much attention. It has six forks worked on crooked shafts, like the arms of a man, which paddle over and over, and catching up the hay, flit it behind in a finely divided condition. This must prove a great saving of time and labor, and is a fit companion of the horse rake. A manufactory for turning out these implements, is soon to be established in central New-York.

DAIRY AND HOUSEHOLD.—In butter, and particularly cheese, the show was good. In hard-

ware, including stoves and furnaces, the articles were chiefly from Utica and neighborhood. In the domestic hall, sewing machines, silver ware, needle work, specimens of penmanship, photography, pianos, saddlery, stuffed birds, coal oil, shell work, wax work, paints, ornamental iron work, Duryea's maizena and starch, domestic wines, fans, boots and shoes were mixed up in delightful order. Here too, was a novel scene; three elderly ladies were seated on a side platform, spinning flax on ancient spinning wheels, after the manner of our grandmothers. These spinners belonged to some of the most respectable families in Saratoga County.

ANIMALS.—The show of stock, though not large, was of superior merit. Ayrshires, Durhams, Devons, Short-Horns, Herefords, and Alderneys, were well represented. The Herefords of Hon. Erastus Corning, of Albany, struck us as remarkably fine. In sheep, we observed Spanish Merinos, full blooded Silesians and their crosses, South Downs, Shropshires and Leicesters. A few Cashmere goats were exhibited. In swine and poultry, Jefferson County alone outdid the rest of the State. The horse department was never better filled, in matched and single, in trained saddle horses, stallions, and mules. One of Secretary Seward's Arabians attracted much curiosity. A noted horse-tamer, "Professor" Rockwell, drew a crowd to the track several times during the fair, by his feats of driving a team of high-spirited horses without bridle, reins, or breeching, controlling his horses solely by voice and whip.

In **FRUITS AND FLOWERS**, the show was creditable, though not large. The pears, plums, nectarines, and grapes, from Ellwanger & Barry, Rochester, were a marked feature. Mr. Smith, of Syracuse, was only a little behind the former. Dr. Underhill of Croton Point, had a fine show of grapes, as did the Pleasant Valley Co. of Hammondsport, Mr. Sylvester of Lyons, Mr. Brehm of Waterloo, and others. Not to be forgotten, was the show of Adirondac grapes,

by Mr. Bailey, of Plattsburgh, not fully ripe, but considerably in advance of the Dianas, Concord, and Isabellas grown in the same garden. The quality, as judged by these specimens two thirds ripe, was very good. Several of Rogers' Hybrids were exhibited, but only one of them seemed thoroughly ripe. The floral display was below the average of State fairs. Yet the show of dahlias was excellent, and there were choice small collections of roses, verbenas, petunias, pansies, stocks, double zinnias, asters and gladioli. The indefatigable Mrs. Van Namee, of Pittstown, was on hand in full force, and contributed much to the fulness and richness of the exhibition.

DISCUSSIONS.—Each evening was devoted to the discussion of agricultural topics, at the City Hall. For the first evening, the subject was: "The most economical mode of supplying the surface soil with the mineral food of plants." For the second: "The best rotation of crops suited to the climatic conditions of the middle tier of counties in this State, on farms having at least eighty acres of good arable land." For the third evening, it was: "The best method of husbandry. The manures obtained from the method proposed, (rotation of crops, etc.,) and the best time of applying them to the several crops, the economy of the management in that respect, on the farms being the same." These subjects were discussed with spirit, and elicited many useful facts. On the whole, therefore, we put down the State Fair of 1863, as a good one.

The International Wheat Show.

The International Wheat Show held at Rochester as announced, did not bring out as large a representation from growers as the importance of the interest and liberality of the premiums, led its originators to expect. We learn from the Genesee Farmer, that there were but six entries for the prize of \$150 for the best 20 bushels of White Winter Wheat. The premium was equally divided between Isaac H. Anderson, of West Flamboro, C. W., and E. S. Hayward, Monroe Co., N. Y. The first exhibited a fine sample of Blue-Stem Wheat weighing 65 pounds per bushel; it was cut July 8th, and yielded 30 bushels per acre. The other parcel was a beautiful sample of Soule's Wheat. For the one hundred dollar prize for the best 20 bushels of Red Winter Wheat, but one lot was offered, by E. A. Hebard, of Canandaigua, N. Y. It was known as the Amber or White Mediterranean, was harvested July 15th, and weighed 62 lbs. per bushel. For the best two bushels of White Winter Wheat there were seven competitors, five of whom offered two-bushel samples of the same wheat as that entered for the twenty-bushel prizes. For the best two bushels of Red Winter Wheat there were three entries; and but one entry for Spring Wheat. Among the lots of White Winter Wheat offered, there was one of twenty bushels grown by Jacob Hinds, Orleans Co., N. Y. In April 1852 he received a sample of Red wheat from the Patent Office, which he thought a Spring variety, and sowed immediately in his garden. It came up and remained green until Fall, but did not head out. The next Spring it came rapidly forward, and early in July produced this white wheat.

It is to be hoped that further efforts will be made to awaken an interest among wheat growers, in the improvement of this first of staples, despite the poor success which seems to have attended the first trial. Perhaps more would enter the lists, were premiums offered previous

to putting in the crop; we should then be likely to learn something of what could be done by high cultivation.

The Fair of The American Institute.

Now that the Fair is a thing of the past, we feel disposed to indulge in a few reflections which may be considered by the managers before they attempt another Exhibition. In former days we used to visit the Annual Fair for the purpose of seeing whatever was new in the way of agricultural machines and implements, and were very sure to be gratified and instructed. This year we went to the Fair with the hope of finding something which would be of interest to our agricultural readers, but with the exception of a single model (with no one to explain it) we saw nothing novel. To be sure there were numerous agricultural implements, but they were things taken directly from the stock of dealers, and were evidently exhibited as an advertisement of their wares. Even these things would have had some interest to many, had they not been so huddled together that it was impossible to get a fair view of them. Those things which could only be judged of when in motion, were so crowded against others as to be motionless, and some articles were not even unpacked. The management excuse this crowding by saying that they had no room. After they had taken such an unsuitable building as the Academy of Music for their Fair, of course everything must be crowded and in confusion. The fruit show was in some respects fine. There were large collections from celebrated nurseries, and as an advertisement of these establishments it was good. We looked in vain for small collections of choice fruit from the hundreds of amateur cultivators around New-York. A stranger visiting the fair would suppose that we had no fruit growers in this vicinity, and that our friends from abroad had undertaken to show us what good fruit was. While we were glad to see these fine displays from cultivators living at a distance, we wondered where our own fruit growers were. The show of vegetables was remarkable—for its poverty. With the exception of a few squashes, potatoes, and onions, there was nothing that a corner grocer in his senses, would buy to retail to his customers. A lot of badly grown turnips, carrots, parsneps, and other roots made up the melancholy show of the Institute. The managers say that they had no room to enable them to invite a large collection of vegetables. If this was the case they should have made no show at all. We are glad for the sake of the exhibitors that they do not depend upon market gardening for a living. We regard this branch of horticulture as one of the greatest importance, and it is one in which every head of a family has an interest. In the vicinity of New-York, kitchen gardening is carried to great perfection, and we hold that a show of its products should be at least up to the average of what could be bought out of a New Jersey or Long Island farm wagon.

As it seems to fall mainly to the American Institute to foster the horticultural interests of this City, we hope measures will be taken another year, to bring out a fair representation of the horticultural products of this community.

HIGH PRICED SHEEP.—At the recent Exhibition of the Vermont State Agricultural Society, Mr. E. S. Stowell, of Cornwall, refused \$1400 for a ram; a farmer in Addison Co., disposed

of three rams at \$1000 each, and another individual in the same district is reported to have refused an offer of \$50,000 for his stock, 200 Merinos. We should say of this latter story as is often remarked concerning news from the South, "it lacks confirmation."

Packing Butter—Suggestions to Country Merchants.

Very large quantities of butter are received weekly in New-York, from country merchants who have taken it in barter for goods. Perhaps it would not be too much to say that the majority of butter sold at this port, for home consumption and for shipping, comes through these channels. From want of skill or of care in preparing it for market, the prices usually realized are far less than might be obtained. It is very unsatisfactory to producers to read in the published price-lists, "butter 23 to 27 cents per lb.," and then have only 15 to 20 cents offered in goods at the store; and they can not credit the statement of the merchant that he can only get that figure for what he sends to the city. Yet such is often the case, and for reasons which might be obviated, some of which are indicated in the following suggestions:—

It is unjust as well as bad policy to pay a uniform price for all butter brought in, as is customary with many dealers. No doubt it is not pleasant to tell a customer that his or her butter is worth less than some neighbor's, but if the same price be paid for all, it is in effect offering a premium on carelessness, and only a second rate article need be expected. It is essential that butter should be of uniform quality and color. To this end it should be sorted as received, and that of similar character packed together. Most of it will need working over to take out the buttermilk, which in "store butter" is usually from two to three per cent in weight. It should be put in the tubs or firkins at once, as soon as worked; and if there be not enough to fill the package, the top layer should be covered with a strong brine. When the package is full, the top should be made even and smooth, a clean piece of muslin, dipped in brine, be laid over it, and salt sprinkled on top of the cloth. The head of the firkin should not touch the butter. The actual weight of the firkin when empty should be plainly marked on the head—two pounds additional tare is allowed in this market for what the keg will soak. Nothing is gained ultimately by marking a false tare; the deception is sure to be discovered in time, and the dishonest party loses credit thereafter. The kind of vessel in which to forward butter to market, depends considerably upon distance from the city, and the time of year. Early in the season, for fresh butter intended for immediate use, or from sections near market, the half-firkin tub (the same as a firkin sawed in two), is generally preferred. Under other circumstances, kegs holding about 100 lbs. are best, and indeed these are almost always salable. For shipping abroad, or for keeping any length of time, none others will answer. The best size and shape are, 22 inches high, 16 inches diameter of bilge, and 12 inches diameter of head, outside measurement; well made of white oak, with smooth, round hickory hoops; the flat-hooped firkins of ash are not liked. No hole should be bored, nor plug put in the head or bottom. The firkins or tubs should be thoroughly soaked in brine, and the sides and bottom rubbed with fine dairy salt. Those who are receiving any considerable quan-

tity of butter, should have a cool well ventilated cellar in which to store it while awaiting a market. No fish, onions, or other strong flavored articles must be kept near it, as butter very soon absorbs any rank effluvia, and its quality is injured.

It is generally found most profitable to send butter forward regularly through the season, while it is fresh and sweet. This, however, will depend upon the rates of the price current. Western butter is the principal supply for shipment during the warm months, and it usually brings better prices than, than if held back until cold weather, when better grades are in market and Western is not so much sought after. In the Winter, store butter ordinarily sells at higher figures in the original rolls, with a clean piece of muslin wrapped around each, and nicely packed in barrels.

How to Pack Eggs for Market.

The following directions for preparing eggs for market were furnished to the *Agriculturist* by Messrs. Surfleet, Meadors & Co., Commission dealers in this city, to whom we are also indebted for some of the hints on forwarding butter, in another column. The profit of shipping eggs to market depends more upon proper packing than to any other circumstance, and it is important to know the best method:

Eggs skillfully packed are received from Ohio, Indiana, Illinois, Wisconsin and Minnesota, in good order, with but few if any broken, and sell more readily and at better prices than those from nearer, which are not so well handled. In the first place, it is a matter of great importance to procure *good sound barrels*, which will stand the usual hazards of transportation; those who make a business of shipping eggs have barrels made to order, strong and well hooped, rather larger than ordinary size, to hold about 75 to 80 dozen; 65 to 70 dozen is as many as can be well packed into an ordinary barrel.

Rye straw, cut into about half inch lengths, or wheat chaff, are more solid, are not so slippery, and are better than oats or any other article in which to pack. Oats as packing are objectionable for many reasons, and *except in extreme hot weather*, should not be used, if rye straw can be had. And even in extreme hot weather the straw would be sufficiently cool, and preferable for eggs shipped by express. Both shippers and buyers generally lose money on the oats; they are also much heavier than straw or chaff, and add considerable to the freight bill, which shippers would do well to consider; in fact those who ship largely and understand the business best, do not pack in oats. A mixture of wheat and chaff and cut rye straw is very much liked by dealers, and much used. Whatever is used should be perfectly clean and dry, to prevent spoiling the eggs by sweating.

Commence by putting two or three inches of packing in bottom of barrel; place the eggs on their sides with butt ends toward the staves and not nearer to sides of barrel than half an inch. Do not crowd them too close together, but separate by at least one eighth of an inch from each other in every direction. Sprinkle the cut straw or packing over the eggs, and rub it well into all the spaces; even off each layer with a circular piece of board or some proper leveller, made for that purpose, separating one layer from another, by about one inch of cut straw. Proceed in this manner with each layer until the barrel is full, when you heap cut straw on

the top, and while you press down the head with one hand rock the barrel backward and forward on end, which will settle the contents as much as they will be likely to. This rocking is particularly important, as the eggs settle into a position from which they will not shift during the whole journey. Fill up with packing, and press the head firmly into its place, and secure it. Be careful not to use too much power, as eggs are in that way often badly broken before leaving the shipper's hands. A lever generally acts with more force than a person thinks, and is not so good as a screw, which is more gradual in its pressure, and the effect more apparent; it also holds the head firmly in its place until fastened. A carpenter or person of any mechanical skill would know how to arrange uprights of proper height, with crossbeam and screw passing through, for this purpose.

Keep correct count and mark the actual contents plainly on the head. A good way is to first count out as many dozen as the barrel should hold, say 75 dozen into a basket or half barrel. A reputation for accurate count is greatly to the advantage of the shipper, besides saving much time and annoyance in correcting errors, and a shipper's marks soon become either favorably or unfavorably known to buyers.

It is usually advisable to make shipments by Express, especially in hot weather, as the extra cost of transportation is quite equalized by the eggs reaching market quicker, fresher, and in better condition, commanding better prices. There is no charge here for cartage on shipments by express, which of itself on small lots nearly saves the additional express charge. Always be sure that your eggs are fresh and sound when packed, as they are carefully examined here, and it is unprofitable to pay freight on rotten eggs.

Mummy Wheat.

In the *American Agriculturist* for September (page 261) we stated that no reliance could be placed on the story that wheat found in Egyptian mummy cases had been grown and the produce disseminated. In a recent number of the *Presse Scientifique des Deux Mondes* (France), is published a description of a series of experiments made by Figari-Bey, on wheat found in the ancient sepulchres of Egypt, and by him reported to the Institute of Alexandria. Two varieties of wheat were tried. The form of the grains had not been changed, but their color both within and without, had become reddish, as if they had been exposed to smoke. On being ground, they yielded a good deal of flour, but were harder than common wheat, and not very friable; the color of the flour was somewhat lighter than that of the outer envelope. Its taste was bitter and bituminous; and when thrown into fire, it emitted a slight but pungent smell. On being sown in moist ground, the grains became soft and swelled a little during the first four days; on the seventh day decomposition was apparent, and on the ninth day it was complete; no trace of germination could be discovered at any time. Both wheat and barley from several different sepulchres were tried with similar results, and the experimenter is of opinion that wheat hitherto reported as obtained from mummy wheat, had proceeded from grain accidentally contained in the mould in which the former was sown, or at any rate not from seed "more than two thousand years old."

During several years past we have from time to time received specimens of wheat, said to

have been derived from mummies, and for which extraordinary qualities were claimed. Advertisements of such wheat have been sent to us, but of course declined, as we have no faith in any stories of the kind—manufactured as wanted.

Hints on Wheat Culture.

We gather the following from an address by Joseph Harris, Esq., of Rochester, N. Y., before the Monroe Agr. Society. He claims that wheat should continue to be the staple crop of the "Genesee Country," despite the midge, or the competition of the Great West. The remedy for the first, is found in high culture that shall make the crop sufficiently abundant to give a good yield per acre, after deducting the amount destroyed by insects; but more particularly bringing it to such early maturity that the midge has no opportunity to work among it. The Mediterranean wheat remains uninjured because of its earliness; if a white wheat ripening at the same time could be found, it would be worth millions of dollars to the country. Much has been said about the exhaustion of the soil, but as long as we can grow good crops of clover, the soil is capable of yielding good crops of wheat. So far as merely enriching the soil is concerned, it makes little difference whether we plow under the clover, or feed it to animals and apply the manure. If we plow in the clover instead of eating it off with sheep, we furnish the soil with a large amount of carbonaceous matter. But this carbonaceous matter is not needed for wheat. In fact, the wheat would usually be better without it, as it has a tendency to retard the ripening of the crop. It is probable that the immense quantity of clover which has been plowed under in Western New-York, has been one reason why the wheat crop has been injured so much by the midge.* Had the clover been eaten off the land by sheep, or made into hay and the manure returned to the land, the wheat would probably have ripened earlier and escaped the midge. It is desirable to see more wheat raised in that section during the next twenty years than at any former period, but it should be done by sowing *less land* instead of more. Plowing in clover has an undoubted tendency to produce an excessive growth of straw, and the use of poor manure will produce the same result. On rich land salt will check this tendency. In some experiments made recently on the farm of the Royal Agricultural Society in England, an unmanured plot of wheat produced 29 bushels per acre, and a plot dressed with 3 cwt. of common salt yielded 38½ bushels, or an increase of 9¼ bushels per acre. John Johnston of Seneca Co. thinks there is nothing better than salt for stiffening the straw. He sows a barrel per acre, just before sowing the wheat. Lime is also a splendid manure for producing plump heads of wheat and a stiff straw.

In regard to competition at the West, there need be little fear. Our soil is better adapted to wheat than most of the land in that region, and the freight is equivalent to a protective duty. In the production of beef, pork, mutton and wool the West has the advantage of us, and we shall be obliged to submit to a much keener competition in the production of these articles.

* It is doubtful whether farmers in Western N. Y. will agree with Mr. Harris. Our own experience in growing wheat in that region was decidedly in favor of turning under a good growth of clover, especially on moderately compact land. It both lightened the soil and furnished the nitrogenous elements, so useful to wheat. Let us hear from practical men.—ED.

Method of Fastening Cattle in Stalls.

The above illustration represents a plan for confining cattle in stalls, practised by B. Hathaway, Cass Co., Mich., who writes concerning it to the *Agriculturist*: "Some years since, in constructing quarters for my cattle, after considering the different plans in vogue for stalling, or fastening, I adopted that of tying; but I have never been wholly satisfied with the arrangement, any more than have my stock. Last Winter I gave my stables an overhauling, and have constructed stalls after a new plan, differing from anything I have ever seen, and, as I think, possessing some marked advantages over stanchion or rope, in simplicity, security, and comfort.

A stable best suited to this plan should be at least fifteen feet wide. The manger would occupy three feet, leaving twelve for the stalls; and another foot would not be thrown away. The stalls are formed of a permanent partition seven feet long, and a small gate hung at the side of the barn, on a line with the partition, which when shut, will complete the stall. These gates, made light, can be opened and shut in a moment. They should be hung so that when unfastened, they will swing back out of the way. There is left a clear passage for stock, or the removal of the manure, of some five feet.

With safe fastenings for the gates, that the cattle can not open, there is the utmost security from their injuring each other, and with three and a half to four feet of width of stall, they will feel abundantly the sense of liberty and comfort.

American Sheep in Europe.

At the Wool Growers' Convention held at Rutland, during the progress of the Vermont State Fair, Col. Daniel Needham, the delegate from Vermont to the International Exhibition of Hamburg, gave an interesting account of the successful competition of Mr. George Campbell's 12 Merinos with the best flocks of Europe, mention of which was made in the September *Agriculturist*. (We glean from a report in the *New-England Farmer*.) He said it required a considerable stock of presumption and confidence to sally out from a Green Mountain home, with sheep from the pastures of Vermont, to compete against those of the imperial flocks in France and the German States; and their forebodings were not rendered less unpleasant, when, on the outward passage, they were informed by intelligent German *connoisseurs*, that for the Americans to enter into such a competition, would be simply for them to roll in the mud, as a premium for their 12 little sheep would be entirely out of the question. However, having made the venture, it was not in Yankee nature to "back down." The Committee of awards consisted of 18 gentlemen, most of them noblemen, and all thoroughly competent judges. Despite the attempt of the German Press to forestall public sentiment against

the American sheep, the subcommittee of this body agreed upon bestowing two first premiums and one second premium upon them, and this award was subsequently ratified by the unanimous action of the general Committee. Mr. N. related that the time appointed for the examination of the sheep by the Committee, was 6 A. M., and that on going to the rendezvous at two minutes past that hour, he found that every man belonging to that body had already reported himself and entered upon his respective duties—an example of punctuality worthy of universal imitation. The 12 American sheep competed against 1,761 foreign sheep, 60 of which were contributed by the Emperor of the French, and were shown in a separate and costly enclosure. At the close of the exhibition, Count Sher Thoss purchased Mr. Campbell's little flock of 12 merinoes, for \$5000.

Salt Needed by Sheep.

An English writer, Dr. Phipson, in a Prize Essay on common salt, relates that not many years ago a German Agriculturist, Uberacker, made the following experiments to determine the influence of salt upon his sheep, which were kept on low damp pasture land: Ten animals were selected, and their usual allowance of salt withheld. In the first year five of this number died of rot and worms, while among the remainder of the flock, numbering over four hundred, only four sheep were lost. The second year a new lot of ten sheep deprived of salt, lost seven, and a short time after the close of the year, the other three of the unsalted number died; the remainder of the flock lost only five. The third year was very rainy; sixteen sheep were deprived of salt, and the whole of them died of rot and vermicular pneumonia.

Improved Hay Knife.

Mr. Wm. S. Wilson, Mifflin Co., Pa., sends to the *American Agriculturist* a description of the hay knife illustrated in the accompanying engraving, which he thinks superior to those in general use. The cutting part is in fish-tail form, made of cast steel, 3-16ths inch thick, 2 inches broad at the top, tapering toward the points, and ground to an edge on the inner sides. The prongs are about 7 inches long, and spread about 6 inches at the points. The handle is a rod of 3/4 inch round iron, of convenient length, say 30 inches, neatly welded to the knife. It is bent outward at the top, to keep the hands from the edges of the hay, when cutting down a stack or mow, and furnished with a cross-piece, for convenience in handling it; or the iron rod itself may be turned to make a loop at the upper end. The horizontal bar, a short distance (about 18 inches) above the blade, is a foot-piece, by which the knife is driven into the hay with more force than could be done by the hand alone. This implement is not patented.

HAY KNIFE.

Hand Corn Sheller.

Various implements for shelling corn are for sale at the agricultural warehouses, any of which are great improvements over thrashing out the grain with a flail or with horses. Where large quantities are to be got out for market, one of these to be run by horse power is almost indispensable. For those who do not require so expensive an apparatus, the implement here illustrated may be desirable. A description of it was furnished to the *Agriculturist* by Mathias Muth, Onondaga Co., N. Y. Its use will doubtless be much easier than shelling by hand over a shovel edge or the cross-bar of the half bushel measure. It is made of a strip of board, about two inches wide and nine inches long, sawed lengthwise through the middle, and the two pieces shaped to the form shown in the engraving. In each of the curved openings are driven nails, such as shoemakers use for heels. The ends, A, A, are fastened together with a hinge of leather. At B, a wooden pin is inserted, passing through the two pieces. This pin is fastened at one end, and is fitted rather loosely into the hole on the opposite side-piece, so that the jaws of the implement can be opened to suit the size of the ears. A better arrangement for this purpose is, to have a metallic spring connecting the two pieces as shown at C, in which case the pin, B, is unnecessary. To use it, take the sheller in the left hand, and with the right, pass first one half of the ear through the opening, then the other half, at the same time giving it a twist; thus with two quick motions it will be speedily shelled. This is an unpatented arrangement, and can be readily made by almost any one having a few common tools.

CORN SHELLER.

For the *American Agriculturist*.

Fancy Poultry.—Some Experience.

MR. EDITOR:—Being one of those farmers who believe in progress, I went into fancy poultry, a few years ago. The huge Shanghai took my fancy particularly, for who couldn't see the profit of having hens nearly as large as sheep, and eggs in proportion? My old fashioned fowls I put into the pot, or sold to my neighbors at a sacrifice. Now, said I, we shall get on. If I don't realize the truth of the old ballad, about that speckled hen that

"Used to lay two eggs a day,
And Sundays she laid three,"

I shall at least get one egg a day from each biddy, large enough to make two of the old sort. Then the origin of these birds struck my fancy. Did they not come from the great empire of China? Did not they or their progenitors flap their wings and crow on top of the famous Chinese wall, or, less aspiring, sun themselves beside it? They were "traveled" hens surely.

And then, what an erect, military carriage! what a lordly step! For the table, what could be in better keeping than a Shanghai cock and a cup of Souchong tea? Both from the same country, they would harmonize well in the stomach, and make pleasant digestion also.

Well Sir, the high-bred birds were bought—at rather a high figure, my neighbors hinted—but I thought them cheap at any price. I confess it troubled me somewhat to see how voraciously they ate up my corn, but would it not surely come back again fourfold in mammoth eggs, and in the broods of imperial chickens?

But Sir, after a pretty fair trial of this fancy stock, I acknowledge myself a little tired of it. They are lazy, they won't scratch for a living, as my former hens did, but prefer being fed from the granary. Nor do they lay so very freely either, after all my care in feeding and nursing, and making enticing nests with glass eggs in the middle. "So much for trying to have 'blood stock'," says my wife, who wants eggs for her puddings and cake. Nor have they proved good setters, while some of them have shown themselves bad mothers. I knew that the rascally sow would sometimes devour her squeaklings, but that the hen, the very image of maternal tenderness, should destroy her brood, was a new and sad thing to learn! One old biddy killed six chicks as soon as born, and raised only three, out of a nest of twelve eggs.

Do you, Sir, like the looks of these fowls? It grieved me at first, to wring the necks of my beautiful Polands, in order to make room for these awkward fellows; but I hoped I should learn to admire them; and if not, their utility would certainly atone for their ungainliness. But their beauty does not yet appear, nor their utility. Their huge carcasses roll and tumble about without anything like "the poetry of motion," and their feathers seem stuck on wrong end foremost. I have often wished their tails and wings were better furnished with feathers, for looks' sake; but I now remember that the man of whom I bought them said they were eminently domestic, had no filibustering propensities, would not try to fly over a fence, and could not; they preferred to stay at home in dignified retirement and be fed, and Nature had given them a plumage suited to their desires.

"Their sober wishes never learned to stray."

And then, as to their crowing, did you ever hear the like! They go it strong, but it is of the Chinese gong style of music—a most dolorous, unearthly howling, long drawn out. The editor of a paper out here, whom my cocks have disturbed with their bass solos, says: "Their crow is not the honest Saxon crow, expressive of day-break, love, war and animal spirits, but a horrid, guttural ejaculation, between a Chinese sentence, as described by missionaries, and a badly blown dinner horn." The editor is regarded here as a good judge of music.

Well Sir, to cut this matter short, let me say that I am convinced that while these fowls grow to about double the size of common poultry, they have likewise double the weight of bones; that while the cost of a hundred pounds of them is more than of a hundred pounds of the old kind, they are less salable, and less inviting on the table. These "celestials" often eat their heads off before fully grown and fattened. I am satisfied that the more I raise of them, the poorer I shall be. I have seen the elephant. My poultry is for sale. CHANTICLEER.

Those who have lost faith in the celestials, and still want to raise "thorough-bred" poultry,

might try the Black Spanish, Black Poland, Irish Game, Dorking, or Dominique fowls.—ED.

Another Wagon Jack.

A subscriber to the *Agriculturist* at Pylesville, Md., sends a sketch and description of the implement illustrated below, which he thinks superior to the one described on page 77. To make it, take a piece of hickory or white oak scantling, 2½ inches square and 28 inches long, and rip it lengthwise through the center a distance of 25 inches: saw off the shorter leg B, at this length, and join it again to A, by a strong hinge. In the

upper end and on the inside of the short leg, B, cut 4 notches, 1½ inches apart, 2 inches wide and ¾ inch deep. Procure a band made of ¾ inch iron, 2 inches wide and 4 or 5 inches long to fit the notches in B. A wooden wedge or key, C, is to be inserted in the band to hold it in the notch. When used, this key is to be placed under the axle, the jack being in the position shown at Fig. 1; then by raising the long leg to an upright position, as in Fig. 2, the axle and wheel will be lifted from the ground, and the apparatus will stand without fastening. We judge it will be necessary to block the forward wheels to keep the wagon in place.

A Caterpillar Burner.

Such is the title given to the apparatus here illustrated, devised by a subscriber to the *American Agriculturist* at Mount Vernon, N. Y. It consists of an inverted cone, C, made of tin or sheet iron, containing a wire grate, A. At B, small openings are made in the cone to allow a draft of air. The whole is received by a socket of suitable shape on the end of a handle of any desired length. Shavings or other light materials are burned in the cone, which is held directly under the nests, and those that drop singed or half roasted, are either completely cooked in the fire beneath, or are caught in the

vessel, whence they may be emptied and crushed. Without some such provision for catching them when burning their houses, many will fall to the ground and ultimately escape. There are objections, however, to attacking caterpillars in this way; in the danger of injuring the smaller limbs with fire. We prefer a spiral brush with which the web, caterpillars and all, may be wound up and put out of the way. An occasional examination of trees when the leaves are off, will detect the clusters of eggs from

which next year's crop is to be hatched, and their destruction will prevent their further mischief. A small premium for each cluster, offered to boys for this work, would soon clear them out.

The New Silk Worm.

Many readers of the *Agriculturist* will remember the account given in a former volume (1861, March No.), accompanied with an illustration, of a new silk worm said to have been imported into France from China, which fed upon the Ailanthus. We have made repeated efforts to obtain eggs of the insect for experiment, but thus far without success, and until recently have heard little further concerning the result of the trials made with it in Europe. In the report of the Acclimatization Society in England, we find an account of experiments made by Lady Dorothy Nevill, near Petersfield, England. One who visited the premises says, "a portion of the garden was planted with young Ailanthus trees, which were covered with a light canvas-made building, a necessary precaution against birds, which pick off the young worms. The creatures were feeding on these trees, and were really beautiful to look at—not pale-looking things like the common silk-worm, but magnificent fellows, from 2½ to 3 inches long, of an intense emerald green color, with the tubercles tipped with a gorgeous marine blue. Their feet have great adhesive power, and their bodies are covered with a fine down which turns the rain drops like the tiny hairs on the leaf of a cabbage, so that they are not injured by wind or rain. Of 500 worms placed upon the trees the previous Summer, 480 yielded cocoons. A market was found for all she could grow, a gentleman in Paris taking them for French manufacture."

The Society above named are enthusiastic in the belief that the raising of the worms can be profitably conducted in England, so that, ultimately, ladies may grow their own silk dresses in their gardens. Speculators in this country will doubtless soon be on hand with great stories, and eggs at marvelous prices, but the memory of the silk-raising and mulberry fever that found so many victims here, is yet too recent, we trust, to allow a similar mania for the new silk worm. We shall continue to watch the matter and report from time to time.

Two Queen Bees in a Hive.

R. B. Olcott, Union Co., Pa., contributes to the *American Agriculturist* an account of the following singular occurrence which he noticed in his apiary. He says: "Some time in July last, having a queen bee at my disposal, and not wishing to destroy her myself, I put her to the entrance of a late second swarm in which she readily entered. Wishing (Sept. 1st) to use this colony to raise Italian queens, I removed the queen, and in returning the combs, to my astonishment I found another queen. This puzzled me considerably, as I never noticed or heard of such a thing before. I returned the queen I had removed, and then took out the combs, leaving the two queens and part of the bees in the hive. I watched them several hours to see whether the queens would quarrel if they should meet. The bees kept a constant running about the hive, and the queens came in contact several times, but apparently did not notice each other, with the exception that at one time one took hold of the other's wing and held her for a second or so, but soon passed on. I then trans-

ferred the queens with part of the bees to an observing hive containing one comb, in order to notice their actions. When not molested, the queens moved about the comb apparently unconcerned. I kept them so for 48 hours, then returned one to the hive, and gave them an empty comb to ascertain if these queens were both fertile. This comb was soon supplied with eggs. I then removed this queen and introduced the other, but egg laying continued as before. I then returned the other queen to the hive. I have examined the colony frequently since, and always found the queens among the bees, but never on the same comb. Whether one of these queens was that which I had introduced in July, I can not say, but it appears likely. This verifies the old saying that there are exceptions to all rules. Has a similar case been noticed before? I shall endeavor if possible to winter this swarm, to ascertain if these queens will remain together a whole season.

Bees Working in Two Hives.

The following remarkable incident is related by a correspondent of the London Agricultural Gazette: "On the 20th of June this year, I hived a very large swarm of bees in a straw hive. Before they had been in it many days, they discovered an unoccupied hive about two feet distant from their own, half filled with clean, empty combs. They sagaciously took possession of it, and used it as a storehouse for honey, while combs were being constructed in their new domicile. At night they did not abandon their store-house, but left a guard of about 500 bees, who remained there contentedly, without any apparent concern at the absence of the queen. This hive was made of wood, with glass windows, so that I could examine the interior, day and night. I could see the honey in the combs, and the bees clustered between them, and coming out by hundreds to the glass, when I held a light to it at night. During the day, the bees at the mouth of the storehouse hive buzzed and ventilated, just as if the queen had been there. At dusk, some of them flew to their own home. After using the extra hive for about three weeks, the bees removed the honey from it to their permanent abode, it being no longer required for the harvest which was for the time too abundant for their accommodation at home."

Things Surprising to a Foreigner.

Mr. Harris, of the Genesee Farmer, says that when he first came from England to this country many things surprised him: "I was surprised at the excellence of American beef and the inferiority of American mutton, and I was not surprised that the beef sold for half as much again as the mutton, while in London, mutton was worth a cent a pound more than beef. I was surprised that farmers paid so little attention to their gardens. I was surprised to find so many farmers with large, handsome houses and elegantly furnished parlors that they seldom used. In England at that time, we had a window tax, and the houses there have few windows. One of the first things that struck me was the number of windows in American houses, and the great effort that was made to shut them up and exclude the glorious American sunshine and the invigorating American atmosphere. I was surprised that everywhere I went, the people thought that particular spot the most fertile, the healthiest, and the best place

on the whole Continent. I was surprised, nevertheless, that everybody was willing to sell. I was surprised at the excellence of the wheat and the inferiority of the barley. I was surprised to see the farmers so rough looking, and yet so intelligent. I was surprised to see the country ladies so much better looking than the men, and withal so interesting and fascinating. I was surprised that farmers sowed but one kind of grass-seed, and that they paid so little attention to their permanent meadows. I was surprised to see them plow so wide, and still more surprised that under the influence of our cold winters, and dry, hot summers, these wide furrows tumbled all to pieces and formed, after all, a very fair seed-bed. I was surprised that farmers raised so few peas and beans, and thought so lightly of clover-hay. I was surprised that farmers could make a living from crops of wheat of from ten to twelve bushels per acre. I was surprised to hear rotten straw called manure. I was surprised at many other things—at the great net-work of railroads—at the magnificent rivers and lakes—at the marvelous rapidity with which the country was settled, and at the enterprise and practical intelligence which has accomplished such astonishing results in so short a time. But I do not think that any one thing surprised me more than this: *the luxuriance of the clover crop in Western New-York!* I had just come from the very fountain-head of agricultural science, and from the greatest experimenting farm in the world; but never had I seen such crops of clover as I saw on many farms in this section."

The Moon Again.

A subscriber in Tuscarawas Co., O., writes: "It would please a good many of your readers, if in your next issue you would give your views as to picking apples, sowing wheat, building fence, etc., etc., during certain stages of the moon." We had supposed our views on the "moon question" were already well understood. The moon is present *above* the horizon during just about half of *every* 24 hours, though her dark side is towards us part of each month, so that we do not see her. The moon passing over us affects the tides regularly every day, and if she affects vegetation at all, the influence is as regular as the tide, and it is doubtless too small to be taken into account. A little knowledge of astronomy will dispel this moon farming. We say, plant, dig, built fences, pick apples, etc., when the soil, the season, and other things are right; the moon will do her part whether her bright or her invisible face be turned towards us.

Honey From Italian Bees.

R. B. Olcott, Union Co., Pa., in answer to questions in the Sept. *Agriculturist*, page 269, concerning the *quality* of the honey gathered by Italian Bees, writes to the following purport. He has kept them two seasons, and considers them 50 per cent more prolific than the common sort. The honey this season he thinks superior, which he says is due to the fact that in his neighborhood there was a great surplus of cherries, from which, as they decayed, the common bees gathered considerable stores, while the Italians were busy with red clover. They also worked among it while the others were among the buckwheat blossoms. He says the Italians will gather almost as much from the second crop of red clover, as is usually secured from buckwheat,

We should like to hear further evidence, particularly with regard to their ability to draw honey from red clover—a point not yet admitted.

Obstructions in Drains—Serious Difficulty.

A correspondent of the N. E. Farmer, states that he has found a difficulty, thus far insuperable, in his drains becoming obstructed with a deposit from the water. The tiles were laid in a swamp, the water of which was strongly impregnated with oxide of iron. In a year or two this completely filled the tiles with a slimy incrustation which stopped the flow of water, and rendered the drain worthless. A partial remedy was found for the main drain, as follows: A cast iron box with a movable cover was substituted for a tile, at intervals of about 100 feet along the whole length of the drain. He then took 12 "Brazier's rods" (4 inch iron, 10 feet long), linked them together by eyes on the ends of each, first drawing the end of the rod a little smaller, so as to bend the point around the rod, to prevent it coming apart in the drain. Two lamp chimney brushes were bound together, to make a brush of proper size, and fastened with a copper wire on one end; on the other end was a swab of ball shape. Then the brush end was put into the outlet, and pushed along by means of the rod up to the first cast iron box, from that to the second, and so on the whole length of the drain, and then run back in the same manner. The water washed out obstructions as they were loosened; the ball allowed the brush to slide over any projections in the tile. This left the drain clean, and was so far satisfactory; but the laterals, he says, could not be so reached. This, however, would seem practicable by beginning at their commencement, and working along toward their entrance into the main drain.

Hints on Feeding and Fattening.

Animals destined for the shambles are disposed of to the butcher to the best advantage, if well fattened. The reason is that the flesh of a fat animal is better than that of a lean one, more delicate in flavor, tenderer, sweeter, juicier,—this aside from the value of the fat itself. A very fat animal is not in a natural condition, and on this account it is desirable that the feeding should be brought as rapidly and steadily as possible to a consummation. It is most undesirable to have any check to the steady laying on of flesh and fat; positive falling off in flesh is with sheep usually fatal to their ever fattening well. Fattening animals are peculiarly liable to certain obscure disorders, owing to the unnatural circumstances in which they are placed. Good farmers therefore exert themselves to keep stock stalled for fattening, healthy, by giving them the comfort of clean stalls, the tonic of fresh air, the increased appetite accompanying a variety or change of diet, a healthy skin secured by occasional currying, now and then a little salt as an appetizer, and to secure freedom from anxiety by quiet surroundings, regular feeding, and the kindest treatment.

In feeding swine, which are the most easily fattened of our domestic animals, great economy may be exercised by feeding very regularly, by cooking the food, by occasionally feeding raw roots in small messes as a general corrective, by feeding finely broken up charcoal now and then, or giving the hogs access to it, and securing cleanliness where they are fed in pens. It is well to remove from such hogs the inducement

to exercise in rooting, by wiring their noses.

A hard worked ox will never grow fat. The more work he does, the less will he lay on fat, the amount of food being equal; and conversely, the less he works, the more easily will he fatten. Used in a "horse-power," he may grind much corn; standing in his stall he may grind only that which he himself consumes. Labor is expended in both cases, and why may we not argue that the fattening of the animal is retarded in proportion to the amount of labor he does, and that the labor of the beast in grinding his own corn is thus a loss to the farmer. Cooked feed digests more easily than raw; that is, the stomach labors less. Do we not profit therefore in cooking the food, even of neat stock? In feeding this class of animals the moderate fermentation of hay and stalks in connection with bran or corn meal and a little salt, whereby the stalks become softened and the flavor of the meal and salt is disseminated throughout the mass, has been found a great saving. This is cooking without fuel. Steaming of fodder is extensively practised also, as is well known, with economical results where it is conducted on a sufficiently large scale and with requisite care. Sheep are best fed on raw material. Let them grind their own grists. For some reason they seem to have better health for it. The exception does not militate against the rule, but shows the necessity of watching the effect upon all animals of artificial diet and unnatural surroundings.

Cranberry Culture.

Several subscribers at the West ask us for some hints upon the cultivation of Cranberries. We have published in former volumes of the *Agriculturist* extended details upon this subject, and have now only space for the essential points.* As the cranberry grows naturally in low places, its most successful culture is practised in similar localities. Almost any bog meadow can be converted into a cranberry patch with fair prospect of success, but the most suitable place is one which is so situated that it can be flowed at will, and yet be capable of being drained so that no stagnant water will remain. The soil should be surface drained; all bushes, stumps, and tussocks removed, and the whole leveled as far as possible. The surface should be burned over to kill the grasses, and then cover the meadow with three or four inches of sand. If sand can not be obtained, it is recommended to leave the ground to the action of frosts for one Winter, after it is cleared and levelled. With regard to the vines, they may be purchased from those who already have good varieties in cultivation, or they may be selected from natural bogs where the vines bear abundantly. The cranberry, like all our wild fruits, presents considerable variety in shape and in the prolific character of the plants, and it will be useless to plant vines from an unproductive natural sort. It often happens that the finest looking plants are shy bearers; hence, where there is any doubt about getting wild vines which are good bearers, it is safer to buy of those who have reliable plants for sale. The planting may be done in October and November, or in Spring, any time until the last of May; where the land can not be flowed, spring planting is preferred. The quickest way to cover the ground is to remove sods of living plants 4 or 6

inches across, and set them out from 2 to 3 feet apart each way. As the sods are apt to contain grasses and other plants, it is much better to break them up and carefully separate the plants, which are put in hills of half a dozen each, at the distance of two feet apart. The planting is rapidly done with the hoe, the principal object being to have the roots well covered. If the planting is done in Autumn, the meadow should be flowed so as to cover the plants with a foot or more of water, which is to be kept on them until danger of spring frosts has passed; it is then gradually drawn off, taking care to leave an inch or two of water as long as there is any fear of frost. The ground should be kept clear of weeds, by the use of the hoe, until the vines spread and get in the way of cultivation; as soon as they mat and cover the ground, they will kill out all other vegetation. The principal enemies to the cranberry grower are, a worm which attacks the young fruit, and which is destroyed by flowing, and the rot, which is prevented by draining. The cranberry has been raised with more or less success on ordinary garden soils, though we are not sufficiently impressed with its practicability to recommend such culture on a large scale. A small plot may be tried as an experiment, and if successful it may be readily extended. The ground is first well pulverized and then covered with an inch or two of muck which has been exposed during the Winter, or with fine sand. The vines are put out in rows 18 inches apart, setting two or three plants together every 6 or 8 inches in the row. They should be set deep, so as to cover 3 or 4 inches of the lower part of the stems, and their growth be favored by keeping out weeds. The kinds known as Bell and Cherry are the best for upland culture, though plants may be obtained on the dry edges of a natural bog which will doubtless do well. Mr. Downing says that a piece twenty feet square will yield sufficient fruit for a family. The Cranberry cultivated in pots, is highly ornamental as a house plant, as is very well shown by a fine specimen now on our Exhibition Tables, from W. H. Starr, of New London, Ct.

A "Community Gardener."—Good Hints.

[The following communication has been sent us by an intelligent and educated gardener, who has had large experience both in this country and Europe. With the growing taste for horticulture in this country, it is quite time that gardening should be recognized as one of the necessary professions, or at least one of the useful arts, and we shall be glad if these suggestions shall help elevate those properly educated for this worthy pursuit to the social rank, which belongs to them. In Europe the scientific horticulturist is an honored member of the community. Sir William Hooker, and Sir Joseph Paxton, were both gardeners, and if we mistake not André Leroy has been knighted by the Emperor of France, in acknowledgement of his contributions to horticulture.—Ed. *Am. Agriculturist*.]

"It is frequently complained by those who have what they call a garden and no proper gardener to take care of it, that they can not secure the services of one, notwithstanding the (as they think) liberal inducements they hold out to a competent man. What is the cause of this difficulty, and how can it be remedied? First of all, it is necessary that one attempting to secure a well qualified gardener, should have employment for such a one. Next, he must be able to appreciate and to properly compensate him. In

both these respects the majority of employers are lacking. A great many want to 'hire a gardener,' who have no place worth the care of a thorough gardener; either the whole concern is too small, or the 'eminent amateur' cares only for something to eat. In either case it will be difficult to find an experienced and intelligent man, who has so little ambition that he will waste his time and energies in such unsatisfactory labor as taking care of these places, or be satisfied with the generally paltry 'wages' that are paid. The demand of the employers generally is: 'I want a man of *experience and intelligence*, and one willing to put his shoulder to the wheel.' Where do they expect such men to come from? America does not produce them, nor will there be any considerable number of American gardeners until there is an entire change made in the social position of the gardener, and a discrimination made between the qualified gardener and him who is merely one in name. The profession of gardener is certainly not an inviting one to young men, when they see how most employers treat those who are engaged by them; very few employers have a friendly word for them, all consider them on a level with the coachman, their place is in the kitchen, and their pay less than any mechanic; and all this, while they are expected to have attainments which can only be found in men of a certain degree of refinement and education.

"Most gentlemen who employ a gardener are men of business, but they do not seem to consider that it requires more knowledge and mental and physical labor on the part of their gardener to properly manage their country places, than is necessary to enable any of their clerks to perform his duties. Yet socially, the clerk is usually considered to be far above the gardener. It is the social estimation in which gardeners are held, and the personal treatment they receive, that keeps young men from entering this branch of industry. It requires taste, talent, time, and money, to enable a young man to qualify himself to lay out grounds well and then properly manage them after they are laid out.

"As the demand for gardeners increases more rapidly than the supply does, or can under the existing state of affairs, I would propose the following suggestions as a partial remedy for the evil. I would advise several gentlemen living in a neighborhood to unite and engage a fully competent man as '*Community Gardener*,' and give him full charge of all their grounds, etc. They would in this way secure a uniform system of management—a matter of great importance to their fruit trees, which suffer most by a frequent change of hands, or rather of heads. A man like this being secured for general superintendence, other and less capable men could be engaged to work under his directions.

"The advantages of this plan will be evident to those who have places too small to warrant them in keeping a competent gardener. In a community where there are large or small places, this having a common superintendent would not only save many vexations and disappointments, but would be much more economical than for each one to attempt to keep a gardener for himself. It would also be a great saving in the item of tools, as one set would answer for several small places; and these should belong to the community gardener, whose interest it would be to have only the best kind, and keep them in proper order for good and speedy execution. I trust that this will commend itself to those who live in parks on a plan like that of the Llewellyn Park, at North Orange, N. J."

* Those at all interested in Cranberry culture, will do well to procure one of the books on the subject, named in our book list in the advertising columns. These are not perfect works, but they are the best published as yet.

THE EMIGRANT'S FAREWELL. — FROM A PAINTING IN THE INTERNATIONAL EXHIBITION, BY CARL HUEBNER.
Engraved for the American Agriculturist.

The scene sketched above, will cause mingled feelings of pleasure and pain in thousands of hearts. However the emigrant may have prospered here in his new home, the love of Fatherland can never be extinguished. His lot there may have been among the lowliest, but thoughts of even the rudest cabin where the hours of childhood and youth were passed, will ever awaken tender emotions. Not a few of our readers may recall to mind a scene similar to the above, in their own experience. It represents the preparations of several families for departure to the New World. "In the village in the distance many peasants are dancing and carousing noisily, to drown their parting regrets or vague apprehensions. In touching contrast to these revellers, are the family in the foreground, who have come to take a farewell look at the village graveyard, that sacred spot of earth which will be remembered in the far-off home when all else in the old country is forgotten—where amid the 'rude forefathers of the hamlet,' sleep their own immediate ancestors, and perhaps in some lately-opened grave, one of its most-loved members. There is real, intense grief in the honest faces of the sturdy man and

wife, as if at some recent bereavement. The kneeling sister with her humble package, including the family bible, is less affected, but yet wears an expression of pious sympathy and sorrow. The younger members of the family look on with a heedlessness characteristic of their years and inexperience. The old grand-dame hobbles along to the sad spot with her stick and her bundle, as fast as her rheumatic limbs will carry her. Poor old lady! she has not much to look forward to; unless, indeed, she finds the El Dorado in her family's happiness; her sun will soon set if she ever reaches that land of the West where the sun himself goes to his nightly rest. The black wooden crosses, often covered with wreaths of 'amaranths,' which mark the spot of the humblest grave on the Continent, are suggestive features which we miss in our own places of interment for the poor." Flowers might well be added here.

While it is lamentable that governmental oppression, the existence of hereditary castes, and other defects in the social organization of Europe, make it desirable for so many of her sons and daughters to seek a new home in the West, the evil has its compensations. The emigrant, if

he worthily fills the place opened for him here, not only secures the blessings of competence for himself and family, but is aiding in developing a power that will ameliorate and finally destroy every form of despotism. America is even now a clond upon the horizon of foreign oppressors, and hence their rejoicing in her temporary apparent humiliation. It is cheering to know that in every European country, the people, in whom is the life blood of Nations, appreciate the facts of the issue, and are giving their prayers and efforts to encourage our National government in the mighty struggle. Nor have they lost confidence in the final triumph of the right, as is shown in the remarkable increase of emigration hitherward during the past year. And we may repeat with confidence what we have heretofore stated, that there was never a better time for the poor of the Old World to emigrate to America. They will be sure of a warm reception and abundant employment at paying wages. And though it may be hard to leave loved objects behind, they may ultimately make a home here to which their children will cling with even greater tenacity, and from which no necessity shall ever force them.

For the American Agriculturist.

What Dwarf Pears to Plant.

A note from a Hartford correspondent inquires for better varieties of dwarfs to plant than the Glout Morceau, or Vicar of Winkfield. Whoever plants dwarfs, necessarily makes a venture, unless he have some neighbor who has done pioneer service for him. No one can tell beforehand just what varieties will give the best results in his soil and climate. If we had no experience or observation in our own neighborhood to draw upon, we would take the list of dwarfs recommended in Downing's Fruit Book for the best six or twelve varieties. Most fruit growers would agree in the main upon these varieties, for the list has been adopted, as the result of their experience. This experience is drawn from all the best fruit regions in the Northern States. Any one following this list, would probably get eight pears in a dozen, that would give the best results, in his own garden.

If we had an enterprising neighbor who had been planting dwarf pears, say for ten years, in soil similar to our own, we would rather take his experience for our guide, than the list recommended by Downing, if it should happen to vary in some particulars. As to better varieties than those named by our correspondent, it is not claimed by any that the Vicar of Winkfield is first rate. Col. Wilder has said, that if he could have but one pear it should be this, and we should not quarrel with him in this matter of taste. We do not claim for it that it has no superior in flavor, but, that when well grown, it is good enough for any body. In other respects it has so many good qualities, that no garden ought to be without it. The tree is a good grower on both stocks, the foliage is very beautiful, and hangs on to the last, it bears abundantly every year, the fruit is large, and may be had in good eating condition, with little difficulty, for at least ten weeks in the year. It is well known, and commands a high, though not the highest price in the market. It is adapted to a wide range of soil and climate. What we mean when we say that there are better pears than this, is, that there are those of better flavor, unless this is kept to Mid-winter.

The Glout Morceau, though of the best where it does well, has many faults. It is a late bearer at best, and with most cultivators a very capricious bearer. We have had no crop worth saving since 1858, until the present year. They are very fine this Fall, so far as our observation has extended. Yet the fruit is so good that we are not prepared to exchange it for another, even with this unfavorable experience. It is said to do much better as the tree gets age.

As better varieties for the quince stock than these, we would name the Flemish Beauty, Beurre Diel, Lawrence, Urbaniste, Beurre d'Anjou, Doyenne Boussock, Easter Beurre, and Winter Nelis. Wherever the Duchesse d'Angouleme does well, we would add it to the list. We are informed that the Duchesse does not succeed well in the vicinity of Hartford, Conn.

The true doctrine in regard to dwarf pears is this: let the amateur experiment, and all others, confine themselves to the very few, less than a dozen, varieties that are known to do well in the neighborhood, and that command a good price in the market. It is more than half with the fruit grower, to sell his crop, after he has raised it. A much better new fruit than the Bartlett, would not sell for half its price, simply because it was unknown to the public. The making of a reputation for a fruit is a very

slow process. It has taken sixty years to give the Bartlett its present general popularity. We have abiding faith in the success of dwarf pears. For small gardens, for fruit growers who cater for city markets, and want early results, they are a great institution. We saw last year a large onion garden of several acres, enriched by long cultivation, gradually changing to a dwarf pear orchard. A thousand trees had been planted for several years and the results were all that could be desired. A fortune is in store for the enterprising proprietor, for he knows what varieties to plant, and how to take care of them after planting. Select good market varieties that are known to succeed well upon the quince, plant in good soil, manure liberally with compost, half muck or peat at least, cultivate cleanly, and prune judiciously, and you can hardly fail. So thinks CONNECTICUT.

Rose Bugs Destroying Grapes.

In some localities the rose bugs are so numerous at the time certain grapes are in flower, that they destroy the entire crop by eating the blossoms. At a recent meeting of the New-York Fruit-Growers, T. W. Field alluded to this subject, remarking that the rose bugs came upon his vines in such myriads that it was impossible to destroy, or even drive them away. He said that while the Isabella and Catawba were nearly all destroyed by these pests, the Hartford Prolific and Delaware bloomed too early for them, and the Concord was but slightly affected. If this proves to be the case elsewhere, it will be well for planters to select sorts which flower before the rose bugs make their appearance.

A New Pear—The Vanderpoel.

Some weeks ago we received from Mrs. Mary V. Gilbert, Columbia Co., a package of pears by mail. Coming by this conveyance the fruit was very much crushed, yet as even in this condition it appeared to possess great excellence, we wrote for other samples, which came to us in a perfect state, though rather late to see the fruit in its best condition. We learn from Mrs. G. that she has been in the habit of planting the seed of superior fruit, and that this pear is

from some seed she planted in 1825. It is a good bearer, and produces annually. The two illustrations will give an accurate idea of the size and shape of the pear. The color is of a

SECTION OF VANDERPOEL PEAR.

uniform lemon yellow. The flesh is melting, juicy, sweet, and without any grittiness at the core. The pear has one very desirable quality, it has not the least tendency to rot at the core; several specimens which were more or less decayed at the surface, were entirely sound at the centre. We think it a very promising fruit, and one very well worth the attention of amateurs. The name Vanderpoel was given by the lady who raised it from the seed.

Grapes—The Great Grape Show.

The exhibition of Grapes, announced to be held at the Office of the *American Agriculturist*, opened on the 1st of October. There were nearly fifty exhibitors, and as many of them showed from five to twenty varieties each, it will be seen that the display was a large one. The amount of fruit was nearly doubled after the judges had made their examination, and during the next day—a considerable number of exhibitors having been belated by other shows, and by unfortunate detention of parcels sent by express and railway. A box from Mr. Huseman of Herman, Mo., was nearly spoiled on the way. The names of the exhibitors, as well as the report of the committee of judges, will be found below. This first attempt of holding an exhibition solely of grapes was attended with most gratifying success. We do not say this on account only of the quantity of fruit contributed, but in view of its *quality* and *variety*. We doubt if there has before been such an opportunity for the public to see and compare so great a number of *native* grapes. That this privilege was appreciated was shown by the interested crowds who thronged the room during the closing days of the exhibition. It was particularly pleasing to observe that a large proportion of the visitors were not merely sight-seers, but persons who came to form their judgment on the different varieties, to get the opinions of the numerous cultivators there present, and to make notes for their future guidance. Most of the leading cultivators of grapes, both amateurs

and commercial growers, came in from hundreds of miles around, some from the most distant West. Indeed we never saw together so many persons of good judgment and experience upon any one subject, as were gathered here on Friday. It well repaid us for the trouble and expense of the enterprise, to see the number of this class together around the tables, earnestly engaged in discussing the fruit and in a most friendly spirit. We have no doubt that the culture of the grape will receive from this exhibition an impulse, similar to that imparted to the culture of the strawberry by the shows of that fruit which have been held at the same place. One of the prominent features of the exhibition was a collection of 20 varieties from the Rev. J. Knox of Pittsburgh, Pa. It did not arrive until after the judges had made their award, but it was conceded on all hands that it was by far the finest collection in the room. The grapes did not need Mr. Knox's apology that they had been long picked and had made a long journey, for they had the freshness of recently cut fruit. Whether it was due to Mr. K.'s mode of culture, or to a peculiarity of his locality, we cannot say, but all his fruit had a bloom upon it which added much to its attractiveness.

Among the novelties of the exhibition we mention the Iona, a seedling now fairly before the public for the first time. It attracted much attention from grape growers. Dr. C. W. Grant, the originator, was awarded the first prize for seedlings. The Adirondac was presented by Mr. Bailey of Plattsburgh, N. Y., and was noticeable for the size of its berries and their fine flavor. It received the first prize for quality, by the decision of the majority of the committee. We understand that Mr. Downing dissented entirely from the verdict. If this grape proves as fine in other localities as it is in that where it originated, it will be a decided acquisition. Allen's Hybrid is another of the grapes not generally known. It was shown in fine condition by Mr. Hoag of Newburgh, N. Y. The fruit is white, and has the appearance and flavor of a foreign grape. It was generally regarded as a variety of much promise. We regret that there was not a better display of Rogers' Hybrids. Only two of these were shown, Nos. 4 and 15—by Geo. Seymour & Co., of So. Norwalk, Ct. Mr. S. says that the vines grow finely and the fruit ripens with the Concord. From tasting the single specimens, we are pleased with these grapes and consider them as fruits of fair promise. The Creveling, though past its season, was shown by Mr. Merceron of Catawissa, Pa. The fruit is a fine looking, large berry, and very sweet and pleasant. It is considered by several cultivators as the best very early grape, it being a week or so in advance of the Hartford Prolific. The To Kalon is a very showy and fine variety, large in bunch and berry. We find cultivators differing with regard to its bearing qualities, and the general impression is, that it is a shy bearer. A couple of clusters of Loomis' Honey grape were shown by Peter Raabe of Philadelphia. This is a comparatively new variety. The bunches are fine, the berries large and black, and of a most remarkable sweetness. The vine is said to be hardy. It received a discretionary premium, and is worth looking after by amateurs.

Among the better known sorts we mention the Delaware first, as it was present in larger quantity than any other sort. It is faulty, that the fruit is small, but is an illustration of the adage that "the best things are always put in the smallest parcels." This defect may be in a great measure remedied by the liberal thin-

ning out of the berries. That when the vine acquires age it becomes an abundant bearer, was finely shown by a large fruiting branch contributed by Mr. R. Hale of Otego, N. Y.

The Concord was represented by many fine specimens, most of them covered with the fine bloom which belongs to this kind when well grown. This and the Delaware both have their advocates, who claim for each the first place among the grapes for the million. There are good arguments produced on each side. For ourselves we wish that "the million" had a plenty of both of them. Hartford Prolific was shown by Fuller, Knox, and others, although it was too late for this variety. The vine is a great bearer and is remarkable for the vigor of its growth and healthy character. The fault of dropping its fruit, which some complain of, is remedied by proper pruning and not allowing the vine to overbear. This and the Creveling are the best early grapes yet well disseminated.

Diana. We were much pleased with this fruit as exhibited by Mr. Brehm of Waterloo, N. Y., and by Mr. Knox. The berry is of good size, branches very compact, of a fine lilac color, and quality nearly first rate. The vine is a great bearer and needs close pruning, and is better for covering during Winter.

Clinton. A rather small grape but a strong grower and abundant bearer. It is called a fine wine grape, and when thoroughly ripened, of fair quality for the table. Union Village is a most showy fruit, although it cannot take a high rank for quality. From the size of the berry and bunch it is a very valuable market grape. Herbmont is a very small grape, but the vine is very prolific; fruit very spirited in flavor, and though its size unfits it for a market fruit, it is worthy the attention of amateurs. The vine needs protection. Elsinburgh is a grape much resembling the Herbmont in appearance and has a high vinous flavor much relished by some. There were but very few specimens of the well known varieties of Isabella and Catawba exhibited. These, from their uncertainty, are being replaced in most localities by more reliable and better sorts.—The following is a list of the entries in the order in which they were received.

- No. 1.—Concord under glass: by Wm. Clark, Northampton, Mass.
- No. 2.—Seedling: "Jersey Counsellor," Wm. Plume, Newark, N. J., through C. M. Saxton, Esq.
- No. 3.—Isabella: E. Fitch, Coxsackie, N. Y.
- No. 4.—Rebecca: John Corbett, Morrisania, N. Y.
- No. 5.—Delaware, 2; Allen's Hybrid, 2; Rebecca, 2; Taylor's Bullitt, 1; Diana, 1; Concord, 1; Isabella, 1; Brinkley (foreign out-door), grown on a city lot, 60x25: Geo. W. Martin, Brooklyn, E. D.
- No. 6.—Adirondac: Jno. W. Bailey, Plattsburgh, N. Y.
- No. 7.—Iona, Allen's Hybrid, Delaware and Alexander: John Hoag, by Chas. Downing, Esq., Newburgh, N. Y.
- No. 8.—Delaware, Diana, Concord, Union Village, Elsinburgh, and Anna, from Vineyard of C. M. Beach, West Hartford, Conn.
- No. 9.—Clinton: Jno. McFarlane, New Durham, N. J.
- No. 10.—Diana, Delaware, Herbmont, Concord: Fred. Baumeister, East Newark, N. J.
- No. 11.—Clinton: E. Williams, Mount Clair, N. J.
- No. 12.—Delaware: Reuben Hale, Otego, N. Y.
- No. 13.—Rebecca, Ruland: Chas. S. Schmidt, Palisades.
- No. 14.—Catawba: W. B. Westcott, raised in city yard.
- No. 15.—Seedling: Col. D. S. Dewey, Hartford, Conn.
- No. 16.—Alvey, Concord, Wilmington White, Clinton, Taylor's Bullitt, Isabella, Delaware, Marion, Diana, North American, Rebecca, Louisa: M. Olm, gardener to Orange Judd, Flushing, L. I.
- No. 17.—Delaware, 6 bunches: B. H. Mace, Newburgh.
- No. 18.—Creveling, Isabella, Concord, Diana, Delaware, To Kalon: F. F. Merceron, Catawissa, Pa.
- No. 19.—Palestine, Syrian, Black Hamburg, Muscat of Alexandria, Zinfandel, Black Barbarossa, Reine de Nice: N. Armstrong, Bergen, N. J.
- No. 20.—2 var. Seedling: J. D. Williamson, N. Y. City.
- No. 21.—Allen's Hybrid, Canby's August, Delaware (40 bunches from 1 vine 4 years old): R. W. Holton, Schenectady, N. Y.
- No. 22.—Hartford Prolific, Diana, Clinton: W. Taft, Fordham, N. Y.

- No. 23.—Native Seedling: J. H. Foster Jr., West Newton, Pa.
- No. 24.—Delaware, 3 years old vine: E. O. Eaton, Troy.
- No. 25.—Clinton: G. H. Hite, Morrisania, N. Y.
- No. 26.—Concord, Diana, Clinton: A. G. Baldwin, Hanover, N. J.
- No. 27.—Seedling, Native: Dr. C. W. Grant, Peekskill, N. Y.
- No. 28.—Seedling, from Hungarian, out-door: Mr. Pollock, Morrisania, N. Y.
- No. 29.—Grapes under Glass: S. R. Trembley, Bergen Point, N. J.
- No. 30.—10 Delaware, 10 Diana: F. C. Brehm, Waterloo, N. Y.
- No. 31.—Delaware, Iona, Union Village: C. M. Saxton, New York.
- No. 32.—Delaware, Rebecca, Alvey, Union Village: W. Brockshank, Hudson, N. Y.
- No. 33.—Diana, Herbmont, Delaware, Taylor's Bullitt, Hartford Prolific, Red Traminer, Elsinburgh, Oporto, Alvey, Anna, Miner or Venango, Clinton, Isabella, Wylie, Canby, Concord: A. S. Fuller, Brooklyn, L. I.
- No. 34.—Herbmont, Diana: C. F. Erhardt, Ravenswood.
- No. 35.—Concord: H. S. Young, Poughkeepsie, N. Y.
- No. 36.—Loomis' Honey, Maxatawny: Peter Raabe, Philadelphia, Pa.
- No. 37.—Manhattan: Isaac Buchanan, N. Y.
- No. 38.—Concord, Diana, Delaware, Herbmont, Union Village, Creveling, Canby's August, Elsinburgh, Logan, Mary Ann, Oporto, Louisa, Alvey, Hartford Prolific, Rebecca, Anna, Taylor, Catawba, Isabella, To Kalon: Rev. J. Knox, Pittsburgh, Pa.
- No. 39.—Celestial, Valentine or Wine: Dr. A. K. Underhill, Chilton, N. Y.
- No. 40.—Concord: Judge Whiting, Tubby Hook, N. Y.
- No. 41.—Ontario, Delaware: J. Dingwall, Albany, N. Y.
- No. 42.—Seedling from Isabella: Mrs. S. W. Randall, Middle Island, N. Y.
- No. 43.—Catawba: T. B. Kissam, Jersey City, N. J.
- No. 44.—Muscogee, Diana, Delaware: R. Richards, Tremont, N. J.
- No. 45.—Rogers' Hybrid, No. 4, and 15: Geo. Seymour & Co., South Norwalk, Conn.

Summary.—It will be seen by the above that there were on exhibition 51 different varieties. As the samples averaged about five clusters, the total number of clusters reached about 750—a fine collection surely, when we remember that the majority were of the leading kinds now prominently before the public. It has been said that few specimens of the fruit of the Delaware have been seen. At this single exhibition there were not less than 125 clusters of this variety alone. Of the Concord there were about 60 clusters, and of the Diana some 70 clusters; Isabella 25, New Seedlings, 30 clusters.

JUDGES' REPORT.—PRIZES.

The Judges on Grapes submit the following report:
 Best Native Seedling, which has never before taken a prize, \$10, to Dr. C. W. Grant, of Iona, N. Y., for "Iona."
 Best collection of Native Grapes, \$10, to A. S. Fuller, of Brooklyn.
 Second best do., do., \$5, to M. Olm, Flushing, gardener to Orange Judd, 41 Park-Row, N. Y.
 Best six varieties of Native Grapes, \$4, to F. F. Merceron, Catawissa, Pa.
 Second best do., do., \$2, to George W. Martin, Brooklyn, E. D., N. Y.
 Best four varieties, Native Grapes, \$3, to W. Brockshank, Hudson, N. Y.
 Second best do., do., \$2, to Fred. Baumeister, East Newark, N. J.
 Best five bunches Native Grapes of any kind, quality to rule, \$2, to J. W. Bailey, Plattsburgh, N. Y., for "Adirondac." (Mr. Downing dissenting.)
 Best five bunches Delaware, \$2, to E. O. Eaton, Troy, N. Y.
 Best five bunches Diana, \$2, to F. C. Brehm, Waterloo, N. Y.
 Best five bunches Catawba, \$2, to W. B. Westcott, New-York, (grown in City yard.)
 Best five bunches Concord, \$2, to H. S. Young, Poughkeepsie, N. Y.
 Best five bunches Hartford Prolific, \$2, to W. Taft, Fordham, N. Y.
 Best five bunches Herbmont, \$2, to C. F. Erhardt, Ravenswood, L. I.
 Best five bunches Allen's Hybrid, \$2, to John Hoag, Newburgh, N. Y.
 Discretionary Prize of \$1, to Geo. W. Martin, Brooklyn, N. Y., for Brinkley, grown out of doors.
 Discretionary Prize of \$1, to Peter Raabe, Philadelphia, Pa., for Loomis' Honey, in point of flavor.
 Discretionary Prize of \$3, to N. Armstrong, Bergen, N. J., for collection of hot-house grapes.
 None of the prizes were awarded for foreign grapes, there being no competition under the schedule. For the only lot (containing one bunch of each kind.) the Committee have recommended a discretionary prize.
 With regard to Native Grapes, the Committee are much gratified, particularly with the quality of the fruit, considering the present unfavorable season, and are disposed to commend not only the design of the New-York Fruit Growers' Society, in arranging for this display, so

interesting and instructive, but also the public spirit and enterprise of Mr. Orange Judd, Editor of the *American Agriculturist*, who placed his rooms at the disposal of the Society, and contributed the prize money and entire expense of the Exhibition.

CHAS. DOWNING, WM. CHORLTON,
D. S. DEVEY, ISAAC BUCHANAN,
JOHN DAILEDOUTZE. Committee of Judges.

Crab Apples.

Every housekeeper knows the value of this fruit for sweetmeats and jellies, though few are aware of the number of varieties now in cultivation, presenting a great difference in size and color, and all beautiful. Aside from the use of its fruit, the tree is well worth cultivating for ornament. In Spring it is covered with charming flowers, while the fruit following, remains for several months, and presents a very showy appearance. Crab apples may be grown as standards or as dwarfs, and in either case when loaded with their brilliant fruit, are most attractive objects. There is now upon the Exhibition tables of the *Agriculturist* Office a collection of crab apples from Frost & Co., of the Genesee Valley Nurseries, Rochester, N. Y., which comprises most of the old and new sorts. The largest and finest colored is the Transcendent Crab, and it is difficult to conceive of anything more beautiful than this in the way of fruit.—Most of the crabs are from the *Baccata* variety of the *Pyrus malus* or Siberian Crab, and vary from the size of a currant up to an inch or more in diameter. The "Lady Crab" does not belong to the same variety, and is not a proper crab. It is a very pretty little fruit, about one quarter the size of the common Lady Apple, and like that is an excellent dessert fruit. It makes up in numbers what it lacks in size, for the limbs are actually crowded with them.

Growth and Treatment of Gooseberries.

Geo. H. Hite, Esq., of Morrisania, a successful cultivator of the Gooseberry, sends his method to the *American Agriculturist*. As his communication is rather long, we extract the principal points of interest. Mr. Hite does not follow the usual method of training to a single stem. He plants a bush of one year's growth and allows but a single branch to grow the first year. The second year several shoots will spring up from the root, and as many of these, say 5 or 6, are allowed to grow, as will make a frame work of the bush, and all others are suppressed. He allows these limbs to grow upward, and when side branches appear on them, allows them to grow to the length of 6 or 8 inches and then nips them off to 4 inches. The terminal bud left at the pinching will start and grow a few inches, when it must be pinched back to a single leaf. The next spring he cuts back the side branches to the first pinching. All laterals (branches which spring from the main stems) must be treated in the same manner. The main stems or frame work are allowed to prolong themselves undisturbed, while the side branches are kept short, in the manner above indicated, in order to keep the bush free and open to admit light and air. Mr. Hite prevents mildew, the great obstacle to the cultivation of the foreign sorts. He puts a quart of dry unleached wood ashes into a vessel that will hold about 5 gallons, and pours upon it 3 gallons of boiling water, stirs it for a few minutes, and then fills up the vessel with cold water, the object being to have the solution as hot as the hand can bear without scald-

ing. The application is made by the hot liquid being thrown forcibly into the bush, by means of a good sized garden syringe. The work should be done thoroughly, taking care to drench every berry and every leaf, both on the under and upper side. Early morning, when the dew is on, is the best time for the purpose. The application should be first made as soon as the fruit is formed—and be continued from time to time as signs of mildew appear—until it is mature. By growing his bushes in the manner above described, and persistently syringing them with this solution, Mr. H. succeeds in obtaining the English gooseberries in great perfection. His manner of training leaves the bush open so that the liquid can reach every spot. He adds that the same liquid with the addition of a tablespoonful of sulphur, has been used by him with great success in preventing mildew upon grape vines.

What to Do with the Lantanas.

"E. P. H.," of Poughkeepsie, N. Y., furnishes for the *American Agriculturist*, his experience with this favorite plant as follows: Four years ago a white lantana in my garden seemed to be so flourishing in October, that I determined to try it as a house plant during the Winter. The furnace heat of the house allowed it to do little more than spindle out a poor existence until Spring, all my trouble having been in vain, so far as blossoms were concerned. In May I turned it out into the garden, and then came my reward; for from June until the end of Autumn it was covered with a profusion of its beautiful flowers, and the more they were cut, the greater was their number. Of course it had proved itself too valuable to be lightly discarded, and therefore, it being too large for the house, I sent it to a professional gardener to be kept through the Winter. The same plant is now in my garden, this being its fourth Summer, and it is 5 feet across horizontally in every direction, and 5 feet high. Its trunk is 4½ inches in circumference at the base, and 3 inches, at 1½ feet above the ground, and it is still constantly covered with its beautiful blossoms, which are well shown off against the deep green leaves. I have now two other Lantanas, one the common yellow and the other the deep orange colored, known to some as "the Grand Sultan," which are now in their third Summer, and also thrive equally well with the treatment given to the white. Cared for in this way, the Lantana, instead of being one of the bedding plants, to be ranked with Verbenas and Petunias, becomes a shrub or bush, not like the Weigelias, Deutzias, and Spiræas, covered for a few weeks with beautiful flowers, and then resuming its sober coat of green, but it is always in its holiday dress. Neither is the Lantana thus treated a delicate plant which must be pampered with rich soils and fed with liquid manures, but it thrives in any ordinary garden soil. Now this may be all known to the Editors of the *Agriculturist*, but it was not to me, and I know it is not to many others who will look upon the Lantana as a tolerable little plant, and allow it to die every Fall.

[The Lantana is one of our favorite bedding plants; but when grown in the manner described by our correspondent, it forms a shrub of great beauty, and will repay the trouble of taking up and keeping through the Winter. To those of our readers who do not know the Lantana, we can best describe it as a shrubby kind of verbenas. It bears numerous trusses of small flowers which are shaped somewhat like

those of the verbenas. There are quite a number of colors—white, cream color, yellow, purple and orange. The orange is remarkable for the change which takes place in the color of the flowers: they are of a very light orange when they first open, and gradually change to an orange red. The plants grow very readily from cuttings, and are supplied in the Spring in large quantities by the florists.—Eds.]

Bulbs in Pots.

There are no more beautiful decorations for the parlor or sitting room than Hyacinths, Crocuses, Tulips and other bulbs grown in pots. They are cultivated with great ease, and with a little care, a succession of blooms may be had throughout the Winter. The soil should be light and rich; a sandy loam enriched with well decomposed cow manure; if the loam be not light, a portion of clean sand should be added. Hyacinths are general favorites for their beauty of color and delightful fragrance. In selecting these, choose medium sized heavy bulbs of the single varieties, as these flower much more freely than the double ones. It is also desirable to get an assortment of colors in order to produce strong contrasts. If planted singly, a 5-inch pot will answer, but a much better effect is produced where three bulbs of different colors are planted together in a 7-inch pot. In potting, care should be taken to secure good drainage; place a piece of broken crock over the hole, and on this some coarse fragments of charcoal before putting in the soil. The bulbs should then be planted so as to leave just the crown uncovered. Give the pots a moderate watering, and then set them away in a warm, dark place, watering occasionally, until the earth becomes well filled with roots. The condition of the roots can be examined at any time by inverting the pot in the right hand, which is spread out over the earth; then give the rim of the pot, held in the left hand, a slight tap against the edge of a table or other hard substance. The ball of earth will be loosened and the pot may be carefully lifted off. When plenty of roots are found, the pots may be brought to a light, warm room, and with liberal watering they will soon give spikes of bloom. When the flowering is over and the leaves become yellow, the supply of water should be diminished and the bulbs dried off. When the bulbs are completely ripened, they can be removed from the earth and kept for planting the following Autumn. If not carefully ripened, it is better to plant the bulbs out of doors and take fresh ones for pot culture. By potting bulbs at intervals of a week or two, from now until Christmas, a succession of bloom can be kept up in the house through the Winter.

The little Tulip, called Duc Van Thol, which is a dwarf kind of various colors, is best adapted to pot culture. These may be planted from 3 to 12 in a pot, and treated like Hyacinths. Crocuses are much grown in pots, though the short duration of their flowers renders them less desirable than either Hyacinths or Tulips. A number of them may be planted in a pot and treated as directed above. These bulbs, especially the Hyacinths, are sometimes grown in water in glasses made for the purpose, but they are more trouble, and the bloom is seldom as fine as when in pots. They may also be grown in pure sand or in wet moss, taking care in all cases to keep the bulbs in the dark until they have formed strong roots. Narcissus, Jonquil, Iris, Snowdrop, and Scilla are readily grown in pots and are pleasing home decorations.

What Shall I Do with my Grape Vines?

This question, though not always expressed in these words, forms the burden of numerous letters which have recently been addressed to the *Agriculturist*. We cannot answer these many inquiries separately, but must make a comprehensive reply, leaving it to the intelligence of our readers to apply general principles to their particular cases. — We prefer pruning in the early part of November, to postponing it to a later season, as the cut surface has time to harden and partially heal before severe weather sets in. Those who have followed our

directions given with regard to the young vine planted last Spring, will have this Fall a single stem. This is simply to be cut back to within a foot of the ground. Next Spring, when the buds start, all but two of them are to be rubbed off, and these two allowed to grow during the next Summer, taking care to keep the stems tied to a trellis or a stake, as in fig. 1. The side branches which start are permitted to grow until they have made two or three leaves, and are then pinched back to a single leaf.

It is also well to check the growth of the stem in September, by pinching off the growing point. A vine in this condition, having two strong stems or canes in the second year of its growth, is ready to make two arms to be laid down to the trellis. If the vine is a poor grower and the new canes are too weak to form arms, they are again to be cut to a single bud each, and two new and stronger canes obtained the following year. Whenever two uprights of strong wood are obtained, they are to be cut back to three feet or four feet in length, according to the plan of training proposed. It is from these arms that the upright fruit-bearing wood is to grow. If the vine is intended to cover a trellis 6 or 8 feet high, the arms should be 3 feet long, and if the trellis is to be only 4 or 5 feet high, the arms may be 4 feet each. The next Spring the arms are to be fastened to the lower bar of the trellis, which may be built with wooden slats, on the plan of Mr. Knox, described in the April *Agriculturist*, or of wire, as directed by Mr. Fuller in the August number. The buds along the arm will all start, and all those which are not needed to form upright canes should be rubbed off, leaving buds—as far as possible upon the upper side—at 8 or 9 inches apart. In this third year of the new vine, the upright canes will be formed, which are to be tied to the trellis, and in a strong vine will bear three or four bunches each. Whichever of the two most generally employed methods of pruning is

adopted, the treatment of the vine up to this point is the same, but the future management is quite different. The mode of training and pruning adopted by Mr. Fuller and many other cultivators, is to grow the vine upon a trellis 4 feet high, and lay down the arms 4 feet in

Fig. 2.—FULLER'S METHOD OF FALL PRUNING.

length each. The treatment of a vine the first Fall after the arms are laid down, and which has single canes from each bud, is to cut back all these uprights to within two buds of the arms; this will leave the vine as represented on the left-hand side of Fig. 2. The next year a cane will proceed from each of these two buds, as shown on the right-hand side of the figure; these are to be kept tied up to the trellis, and allowed that season to grow to the top, where they are pinched off. The Fall of the fourth year, one of the canes is to be cut back to two buds, and the other cut away altogether, as in figure 3; the cross lines show the place of each cutting. By following this treatment each Fall, there will always be produced two upright canes from each spur upon the arm—one of which at every Fall pruning is to be cut back to two buds, and the other one removed altogether. During the Summer, the laterals, which do not bear fruit, are pinched off to a single leaf, and the uprights should be pinched at the third or fourth leaf beyond the last bunch of fruit.

A quite different system of pruning is followed by Mr. Knox and others. The trellis is 8 feet high, and the arms are 3 feet in length; each producing 4 upright canes, which are to have the laterals or side shoots pinched off to a single leaf during the summer, and in September the end of the upright shoot should be pinched off to induce the wood to ripen. The vine in the

Fig. 3.—WHERE TO CUT.

Autumn, after the arms are laid down, will present the appearance shown in fig. 4. The pruning consists in cutting back each alternate cane to two buds only, and shortening in the others according to their strength; thus, a vigorous upright will be left to occupy the whole height of the trellis, while a weak cane is cut back to four feet, more or less. The vines will present an alternation of long canes and of short spurs, each bearing two eyes. The next Spring the long canes will throw out fruit bearing spurs, which after the fruit is set, are to be pinched off at the 3d or 4th leaf beyond the last bunch, and all other laterals stopped off. Upon the short spurs, both buds will start, and the most promising is allowed to grow while the other is removed. New canes will be form-

ed from these buds which will fruit the following year. At the next Fall pruning, the old canes are cut back to two good buds, just as the others were the year before, and the new canes shortened or not, as circumstances may require. In this way of pruning, each alternate shoot is

cut back every other year to buds, only one of which is allowed to grow. The advocates of this system of pruning claim that it is better adapted to our native vines, than the one first described, as ours are such rampant growers that they will not submit to the close confinement required by that.

—Whatever method of pruning is followed, the vines should be removed

from the trellis and laid down at the approach of cold weather, and in northern localities, where the Winter is very severe, covered with a layer of light soil. All varieties of grapes are benefitted by laying down, even if they are not covered. With perfectly hardy varieties, merely removing from the trellis and laying upon the ground, is all that is needed, but more tender sorts, like the Diana, require protection. They may be protected by a covering of soil, if it is not too wet, by cedar boughs, or by a few rough boards carefully laid over them.

Fig. 4.—MR. KNOX'S METHOD OF TRAINING.

Advice is asked of us very frequently about pruning old and neglected vines, by those who wish to get them into a shape for proper training. As such vines differ much as to age, and have been subjected to different degrees of care, or neglect, it is very difficult to give directions without seeing each particular vine. The best way to treat an old vine is, to layer good vigorous branches and start arms from them, as directed above for young vines.

Plants Suited to House Culture.

Persons who visit a florist and buy those plants which flourish well in the green-house, are very apt to find that they droop soon after they are taken home, and if they do not die altogether, they drag out a lingering existence. The conditions of our dwellings are so different, in respect to temperature, moisture, and light, from those of the green-house, that there are but few plants that will stand the change without injury. It is much better to start cuttings out of doors during summer, for winter blooming. Plants obtained in this way will be much

hardier, and will do much better in the house, than those which have been grown in the greenhouse. We name a few readily obtained, which do well in rooms with a fair share of care.

Roses.—These are put at the head of the list as they are such general favorites. Of the China Roses, Agrippina, Sanguinea, are very good sorts; and the India for common monthly. Of Tea Roses; Safrano, Odorata, and some others.

Geraniums.—Rose Geranium, always admired for the fragrance of its foliage, and Tom Thumb or some other of the scarlets for flowers. The Ivy-leaved is pretty for both foliage and flowers, but it should be grown upon a trellis, or in a hanging basket, where it appears very beautiful.

Verbenas.—These make admirable window plants. They can be kept in a compact stocky form by frequently pinching off the shoots.

Petunias.—These do well, but require some care to keep them from growing too straggling.

Heliotrope.—Always desirable for its fragrance. Cuttings started during Summer will make good blooming plants for the Winter following.

Abutilon.—We consider this one of the most desirable plants for the house. It is described and figured in the September *Agriculturist*.

Cuphea.—The little *Cuphea ignea* (sometimes called *platycentra*) is a fine plant for the parlor, being always covered with its brilliant flowers.

For climbers the English and Irish Ivy, and the plant called Mexican or German Ivy will give a refreshing green. These may be run up over the window on strings or wires. The Canary Bird Flower *Tropæolum peregrinum*, and other *Tropæolums*, will do well in a poor soil.

To the above list may be added: Azaleas; Hoya or Wax plant; Calla; Chinese Primroses; and Camellias. The Camellia will, however, seldom bloom in a heated room; the temperature should never be over 65°.

Hints on Drying Apples.

Apples not wanted for family use may be turned to very good account in feeding stock, but they will give much better return by carefully drying them. Although the season for gathering this fruit is mostly past, many barrels will not keep until used at home; if sent to a distant market, freight expenses would consume most of their value, and no better disposition can be made of them than to prepare them for sale in the dried state. The demand for such fruit is at present almost unlimited, and those who prepare it, may not only have the satisfaction of receiving good prices, but also of knowing that a large part of the stock will go to improve the fare of our soldiers, to whom they will be a real luxury. The work may be greatly facilitated with proper apparatus. The "turn-table" apple parer, of which several modifications are to be found at most hardware stores, is a great time and labor saver. Where the amount is small, the coring and slicing may be done with the common knife; but where large quantities are to be prepared, a circular cutter of tin to remove the core and a slicer having several blades which will finish the work at a single stroke, are desirable. At this season most of the drying must be done within doors; and if properly managed, this method is preferable at all times. A drying room may be cheaply fitted up with a stove having the pipe near the floor and extending lengthwise of the room. The frames or racks containing the fruit may be placed in tiers directly over the pipes, and the

drying done very expeditiously. The plan of a convenient drying frame is represented in the

accompanying illustration, designed by one of the editors of the *Journal of Health*. The upright posts of the frame *a*, are two inches square with strips about one inch square nailed across, far enough apart to admit a rack between them, and braced with inch strips at the back, as shown in the engraving. The rack *b*, is four feet long, and about eighteen inches wide, made of common wall lath nailed on a strip at each end, about one fourth of an inch apart, or nearer if required to dry small fruits. Or they could be constructed of "galvanized" wire cloth, which would be preferable, though of course more expensive. A lath or strip of board one inch wide is nailed round the edge, to prevent the fruit falling off. These racks are slipped in upon the side supports as shown in the figure. The legs of the frame may be made sufficiently high to admit of its being placed directly over the stove pipe, from which a current of heated air will pass up among the sliced fruit, and dry it very rapidly. There should be good ventilation of the room to carry off the air as it becomes saturated with moisture. The more rapidly fruit can be dried, without exposure to high heat, the better will be its flavor and color. Drying within doors also has the advantage that flies and other insects can be excluded by mosquito netting at the windows, or openings for ventilation. One or two cents per pound over the ordinary price, which will be readily realized for nicely dried fruit, will in most cases well repay the extra cost of all the needed appliances.

Treatment of the Croup.

A "Physician's Wife," at Carrol Co., Ill., writes to the *American Agriculturist*: "Croup gives warning in advance, and woe to the mother who fails to heed that warning. Last Sunday morning the good of the sermon was lost to me by the dry hacking croup cough of a little boy in one of the front seats. As the sermon progressed the coughing grew deeper and harder, and I thought the services would never get through. A mother in front of me clutched nervously at her shawl every time the little fellow coughed, as if she would fain pull it off and wrap it around the child. There he sat with a low necked jacket on the throat, and part of the chest exposed and bare; the sight of a corpse would hardly have chilled me more. I was a stranger to the lady who sat beside him, but learned it was his mother. 'Do you know your child has got the croup?' said a woman as she came up the aisle. 'Yes, he was croupy last night,' she replied quietly. 'Why don't you tie some thing round his neck then?' said the friend, 'and if you want to save his life, give him an emetic when you get home; rub liniment on his throat and chest, and get him in a perspiration, keep him warm for a day or two and give him light diet.' The mother passed out and I

hope she followed the directions. 'Who is it?' I inquired of the friend. 'O, it's Mrs. Blank,' was the reply, 'it's not two weeks since she buried a child.' There is no disease more simple to cure than croup at its outset, inflammatory croup excepted, and no disease more baffling to physicians when allowed to proceed too far. Now is the croup harvest; one day is warm, another is cold, and in many families the winter clothes are not ready until near Christmas. This ought not to be. Mothers ought always to have some simple remedy on hand for child diseases, for with many families a doctor is so distant, and his being at home so uncertain, that sickness may have made fatal progress before he arrives. The butchering season is at hand now, and it is proverbially croupy. Fresh sausages and pork steak are too tempting for the children's appetites; and the stomach out of order, I have noticed, will bring on croup, nearly as soon as taking cold. A mother who seldom employs a doctor, said to me, 'I have never known an emetic to fail in curing croup if given in time.' It is always used in our family, and always with the same success." [See simple enough remedies in the October *Agriculturist*.—Ed.]

Designs for Ornamenting Cravats.

Miss S. R. Bowman, Philadelphia Co., Pa., contributes to the *Agriculturist* the accompanying designs for ornamenting the ends of gentlemen's silk cravats. They should be worked in fancy colored silks, crimson, blue or buff, to suit the taste and complexion. The edges of the ends may be worked with either points and dots, or finished with a hem, and stitched or chain stitched in one or two rows, with silk to match the principal design. The cravat itself is best made of plain black, either ribbon or dress silk. To our individual taste the plain neckerchief or tie, without any such addition, is more becoming to any gentleman, old or young, but fashion decides otherwise, and most young men will be in the fashion if possible. A neck tie neatly ornamented in this manner would be a very suitable present from a young lady to a gentleman, on the approaching holidays. Articles made by the hands of a friend are more highly valued than those purchased.

How to Fold a Lady's Dress.

Miss S. R. Bowman, Philadelphia Co., Pa., contributes the following directions for the *American Agriculturist*: Take the exact quarters of the dress, from the bottom of the skirt, to the sleeves, double them together with the bosom out; then on a bed, lay the skirt perfectly smooth, and begin at the bottom to fold it up, just the width of the trunk or drawer. The waist and sleeves will fold nicely to

gether, and must be laid outside the folds of the skirt. Then double over the ends, to fit the length of the trunk or valise, and it may be carried very smoothly without taking much room. For a carpet-bag, it is better to roll it, which may be done very tightly without rumpling.

Parlors and Parlor Ornaments.

We Americans are a wonderfully utilitarian people, yet few seem to realize that there is utility in refined enjoyment. We have often alluded to the stiff, dark, shut up parlors or "best rooms", too good to use, and which, while scrupulously neat and furnished with chairs, tables, sofas, and handsome lamps or candlesticks, are so utterly lacking in attractiveness that they would be shunned by every member of the family were the blinds not closed and the curtain down, the air close and every thing kept ever in appropriate order for a funeral. A stranger shown into one of these rooms has nothing to do but twirl his fingers and wait. The blinds are turned and throw an uncertain light into the prevalent obscurity, and there is not a thing to look at but some old fashioned annuals or gift books and the family portraits perhaps. Now it requires a great deal of training to destroy in man or woman the love of the beautiful, and, it is as natural for a girl to put flowers in her hair as to put cherries in her mouth; each act is done for her own enjoyment. Her staid mother regards the fruit as food and the flowers as vanity. So, gradually the natural taste and love for having beautiful things about her is educated out of the daughter of this frugal housewife and excellent mother. The guest who is not a stranger is shown into the "sitting room" or kitchen at once, and receives hospitable welcome that more than takes the place of a welcome which might be extended to the stranger, not in words, but by the pleasant surroundings of a bright, fresh, genial room, adorned with flowers, pictures, and other interesting objects, the windows of which look out upon a pleasant flower garden, grassplot, or distant hills and valleys.

If any young lady reader of the *Agriculturist* knows any such stiff, close, shut up parlor within a mile or two of her comfortable, light, sitting room, and follows our counsels, she will get up bright and early some morning, and first open the windows to see from which the pleasantest views are obtained, and then leave the blinds open and the curtains drawn, at least at the most attractive one. Then she will set the chairs at an easy angle as if somebody had been sitting so that he could cast an occasional glance at the prospect. If there is a centre table, place a few of the most attractive books, engravings, or photographs, she has upon it, and then picking some flowers, arrange them in a plate of sand and moss, or in a loose easy bouquet with pretty green leaves, and place this among the books and pictures, (don't try to make a stiff green-house bouquet); or arrange both the plate and the bouquet, put the former on the table and the latter on the mantelpiece. Now she may draw up the rocking chair near to the centre table, selecting that spot from which the room, the table, and the window will all look prettiest, where also the chair itself will have an inviting, hospitable look to one entering the door. This done, let her take a seat at the window or table, imagine herself a stranger, and think how she would feel. See if the room offers not only a welcome, but attractions which will in a measure make good the lack of her own society, while she is washing her hands, taking off her apron, and making ready to receive her guest. Finally set the door open, and fasten it, if the chronic tendency to stay shut makes it swing to. This is what may be done in a parlor, without outlay either in money or labor for other adornments than those which the garden and library of every well-to-do farmer's family affords.

The outlay of a little money and the exercise of a little good taste will furnish any room with many additional attractions, without considering houseplants which add so much to the agreeableness of any apartment. The multiplication of beautiful

photographic pictures, copies of distinguished works of art, which are sold at very moderate rates, places a most elegant and interesting class of parlor ornaments within the means of almost every one. Really beautiful engravings or lithographs even, are much more expensive—and let us beseech our readers to content themselves with flowers alone, rather than make use of the cheap colored lithographs which are so apt to attract those of uncultivated taste.

Rustic Picture Frames.

Rustic work for this and other purposes is in great favor now-a-days in the fashionable world, and many and beautiful are the imitations of bark, rough wood, leaves, vines and moss upon bark and twigs of trees, etc. These are cast in bronze, zinc and iron, for picture frames and similar purposes. Papier-mache is also pressed into a multitude of rustic forms of great beauty, and the wood carvers exercise their skill in producing in oak, black walnut and butternut, devices representing rural things. With a little care in selection and skill in handling tools, we may frame our photographs and engravings and crayons with rustic work as much more beautiful than the costly products of the bronze foundry, as nature is superior to art. Oak wood denuded of the bark presents a beautifully corrugated surface, out of which the knife easily removes the few fibres which adhere, and it is ready for varnishing as soon as it is seasoned. The "season cracks" should they occur may be filled with dark brown putty and will even lighten the general effect. Natural scars, knots, spots where branches have been removed or only short spurs left, all add greatly to the ornamental effect. Pieces of suitable diameter, sawed carefully in two lengthwise, are very easily worked, matched at the corners, etc., and make strong durable frames. Wood having beautiful bark, not too rough, covered partly perhaps by close clinging lichens, is very pretty, wrought into frames in the same way, and when one once begins to make such things it is remarkable how many beautiful objects he will find ready to his hand.

Preparing for Cold Weather.

The change of temperature from the 90° of Summer to the freezing and zero points of Winter, necessitates no little preparation to secure continued health and comfort. The most important part of this work is to have the body itself in right condition. No extra amount of clothing will secure genial warmth, if the heat-producing organs in the system fail to properly perform their functions. As most readers are aware, our garments are not needed so much to keep the cold out, as to keep in the heat which arises from slow combustion of part of the food in the system. A person with vigorous digestion, active circulation, and a clean skin, will feel comfortable with an amount of clothing under which a dyspeptic or consumptive would shiver with cold. The out-door life of the farmer usually secures the right working of his heat producing apparatus, but the female portion of the community need instruction and care on this point. More out-door exercise is wanted to give tone and vigor to the system, and prepare it for any changes of weather. Some regard should be had to the character of the food, with reference to maintaining animal heat. That containing a large portion of carbon is best fitted for cold weather, as fat meat, buckwheat cakes, etc., which wisely form a large part of the staple provisions in Winter. We repeat a hint frequently given in the *American Agriculturist*, on keeping the feet warm. As they are constantly in use, perspiration is more copious there than in some other parts of the body, and hence the socks soon become damp. In that state they rapidly conduct heat away, and cold extremities and the resulting evils of "taking cold," and other derangements, often follow. The preventive is to wipe the feet dry, and change the socks during the day. Bathing the feet in cold water in the

morning and rubbing them well with a coarse towel will aid in making them less sensitive to cold. It is unwise to defer putting on thicker clothing until late in the Fall. The rapid change from warm to cooler weather in Autumn, is often more trying to the health than the severer cold of settled Winter.

In arrangements for heating dwellings, economy of fuel is worth considering, but not to the disregard of the health of the occupants. It is possible to make a room nearly air tight, and thus keep out every breath of wind that might "bring in the cold," but it would soon become unfit for occupancy. There is very generally great disregard to ventilation, especially in Winter. It is desirable to avoid cold drafts from crevices in the doors and windows, but better leave these, than not provide for the escape of the vitiated air, and the ingress of that which is pure. A ventilating flue connected with the chimney, such as was described in the *Agriculturist*, Vol. XX, p. 309, (Oct., 1861,) is well adapted for this purpose. A large sized stove is more economical and less prejudicial to health than a small one. In the latter it is necessary to keep the fire brisk, and the rapid draft carries away through the pipe a much larger proportion of the heat produced, than would escape were the fire only moderate. The stove must also often be kept nearly or quite red-hot to supply sufficient warmth, and this rapidly spoils the air for breathing. In large stoves, both these difficulties are obviated; the fuel is more slowly consumed, and a more moderate temperature is diffused from the greater surface.

Before putting up stoves and building fires for the Winter, examine all flues and be careful that no defects will allow the escape of fire to ignite surrounding wood-work, and also that there be no danger of conflagration from soot which may have collected during the previous year.

Put Water on the Stove.—Important.

This subject has been referred to in some previous volumes of the *American Agriculturist*, but is so important in respect both to health and comfort, that we refer to it again. Let the reader look a little into the science of the matter; the practical lessons to be learned, will be useful. The air acts upon water like a sponge; it sucks up and secretes more or less of the fluid, but with this difference, viz., that the warmer the air, the more water will it secrete. For illustration, take a room 12 by 15 feet and 9 feet high, which contains 1620 cubic feet of air. This amount of air at the freezing point (32° F.) will contain only 3807 grains, or a little over $\frac{1}{2}$ pint of water. Heat the air to 50°, and it will absorb 6869 grains or very nearly a full pint. Heat the air to 70° or barely to a comfortable summer warmth, and it will absorb 12,863 grains or nearly a quart of water. Heat the same air to a 100° or just above blood warmth, and it will absorb 30,975 grains, or nearly $2\frac{1}{2}$ quarts of water! That is, increasing the temperature, increases the capacity of the air to absorb water. In a cold room the air often feels damp: warm the air by a stove and it becomes dry and unpleasant—the moisture has been absorbed and hidden in the air, and the sponge-like capacity of the air draws the moisture from the skin.

On the contrary, cooling the air lessens its capacity to hold water, and it deposits the surplus. A tumbler of cold water cools the air near it, and the surplus moisture is deposited upon the outside of the glass. The window panes exposed to the outside cold, cool the adjoining air on the inside, and the moisture is deposited on the glass. The air thus cooled sinks down, more warm air takes its place, and more moisture is deposited, until the glass is dripping wet, and, perhaps, the water freezes upon the windows. A cold current of air meets a warmer one in the atmosphere, and chills it; the moisture previously concealed is thrown out in the form of vapor or clouds, and when the deposit is large, the watery particles unite and descend in rain drops. (Digging a soil, that is opening the cooler soil to admit the hot atmosphere, causes a condensation of moisture; hence the advice to hoe frequently to alleviate the effects of a severe drouth.)

The *practical lesson* now aimed at, is, that when we heat the air of a room by a stove or furnace, we make it a drying sponge, and it sucks up the air from the surface of our bodies and from the lungs, and not only produces unpleasant sensations, but injures the health, to say nothing of its drying out and cracking or warping furniture. To remedy this, there should always be an artificial supply of moisture to the air when heated by a stove or furnace. (The open chimney or grate carries off so much air, causing the introduction of fresh cool air, that the dryness is not so greatly felt.) A wide open vessel of water on a stove, partially supplies moisture. But even this is not enough for the greatest comfort and health. A cloth frequently dampened and hung on a chair or frame near the stove, is preferable. Every one must have noted the balmy effect of a few clothes hung on a frame to dry in a hot room. We heat our whole house by a hot-air furnace in the cellar, as being the most economical as well as the most convenient and comfortable method. But the warm air comes up saturated with moisture derived from a wide vessel placed within the furnace cover, just over the fire, and *always* kept supplied with water. The lack of sufficient water apparatus has caused many, otherwise good, furnaces to be thrown aside as disagreeable and unhealthy. The so-called "burned air" is simply deprived of sensible moisture. A stove-heated room may be made far more pleasant by supplying plenty of moisture.

Let Teachers, and Sextons of churches, act upon the above suggestions, and keep a spacious wide-mouthed evaporating vessel upon the stove. If this does not suffice, and at any time the pupils appear specially restless, try the hanging of a few damp handkerchiefs or garments on chairs near the stove. The effect will often be almost magical.

How to Pickle Cucumbers.

In response to several inquiries from *Agriculturist* subscribers, we publish the following directions given by Mrs. Haskell, in her *Housekeepers' Encyclopedia*: Cut the cucumbers from the vines without bruising the stems; lay them carefully in a basket; take them to the cellar; sort and pack them in barrels, putting different sizes in separate barrels, spread a layer of salt between each layer of cucumbers; there should be sufficient salt to entirely cover the pickles between the layers. Continue to pack the cucumbers daily as they are picked, never using any but fine cucumbers, discarding all that are crooked or of slow growth. Keep boards over the pickles, and weight to press them under the brine, which will be formed without the addition of water, with the juice extracted from the fruit by the salt. Pickles packed in this manner may be preserved for years, if there are no impurities in the salt; but if the salt is mixed with lime, they will soon soften and spoil. In two months after the barrel is filled, take them from the brine, freshen and green. To green cucumbers, prepare alum-water; put the pickles in a vat or boiler, lined with tinned copper; heat the alum-water, and pour it over the pickles. This is the process which is usually employed by pickle-makers, except that they throw steam into the vats to heat the alum-water, and if managed properly the pickles may be greened with less action of copper than when scalded in the usual method in bright brass kettles. Take the pickles from the vat when a little green, and pour over them water boiling hot. If not greened sufficiently, repeat the hot water until they are the desired color, and when cold, put them in good vinegar, let them remain until quite soured; then change to pretty strong vinegar, which will keep the pickles hard and sour; add to a barrel six large peppers, without bruising, and keep the pickles under the vinegar with weights.

To Dye with Sumach.—Miss Lizzie M. Coggeshall, Platt Co., Ill., sends the following directions in answer to the inquiry in the October *Agriculturist*: Cover the berries with water and boil them an hour. Strain off the juice and add a

tablespoonful of copperas to each three gallons of the liquid, stirring it in thoroughly while boiling hot. Wet the yarn in warm water, put it into the hot dye, and occasionally stir it up, while the yarn is taking the color. The color will be purple, and it can be made darker, by boiling the berries in an iron pot.—Another correspondent writes: "For one pail of rain water, take 6 qts. of the berries, soak them in iron 24 hours; then take them out and put in the yarn. Stir it often and keep the dye hot, but not boiling, while soaking. If you wish to color black, set it with copperas; it needs no setting unless to color black."

Meals for a Week.

Some months since a correspondent requested through the *Agriculturist* "Basket," that some one would furnish a list of meals for a week which should combine economy and good fare. Several communications have been received, of which we have space but for the following. "H., of Rahway, N. J., writes: "My living expenses being reduced since the war from \$3000 per annum, to less than the fourth part of that sum, economy is the strict rule: and I send you an account of one week's meals of our family of five (three adults and two children, one an infant). The cost is estimated a little too high, as the month just past averaged 15 cents per week less.

Breakfast.—Each morning buckwheat cakes, cold meat, tea and coffee; excepting that on Monday and Thursday, eggs are served instead of cakes.

Dinner.—Sunday, Monday and Tuesday, roast beef, potatoes, turnips, and bread pudding—omitting the pudding on Monday. Wednesday, roast pork, potatoes, turnips and onion sauce. Thursday the same with pancakes. Friday, corned beef, potatoes, turnips and batter pudding. Saturday, the same except bread pudding. Tea at each dinner.

Tea.—Toast, preserves, tea and coffee, and twice, fried kidneys extra.

The cost of the above meals was, say
 14 loaves of bread, 5c. each. 70 10½ lbs. of beef, 8c. 84
 5 lbs. granulated sugar, 15c. 75 5 lbs. of pork, 10c. 50
 2 lbs. brown sugar, 10c. 20 2 beef kidneys, 5c. 10
 1 lb. of coffee, 38 Onions, 10
 ½ lb. of tea, 88c. 22 Syrup, 1 quart. 14
 4 lbs. of buckwheat, 16 3 doz. eggs, 20 cts. 60
 2½ lbs. of butter, 28 cts. 71 ½ lb. flour, 3
 14 pints of milk, 6c. per qt. 42 Nutmeg, yeast, salt. 25
 Total expense for the week \$6.16.

Tea we drink weak; coffee very strong. Potatoes and turnips are my own growing, and preserves made from fruit of our own raising. Beef at 8 cts. is the rump which hung for a week, roasted slowly say 2½ hours, and well basted, is equal if not superior to porterhouse roast."

Another correspondent, "C., of Andover, Mass., gives the following: "**Breakfast.**—Monday, toasted bread, either Graham or brown, also white bread; sauce and cheese, or broiled salt fish.—Tuesday, milk toast and doughnuts, crust coffee or cocoa shells, and boiled eggs.—Wednesday, warm biscuit and molasses gingerbread, with some slices of cold meat left from yesterday's dinner.—Thursday, hot Indian breakfast cake, cold bread, baked apples, cheese, beefsteak and baked potatoes.—Friday, griddle cakes and roasted apples, chocolate or tea, cold bread and hash.—Saturday, toast dipped in hot salted water and buttered, mashed or roasted potatoes, cold meat or boiled eggs, and doughnuts.—Sunday, fish balls, a hot breakfast cake of Graham flour or fried hashy pudding; pickles and horse-radish.

Dinners.—Monday, beefsteak, potatoes, squash, bread and butter, baked apples or sauce, and apple or squash pie.—Tuesday, roast beef, or fresh pork, boiled squash, turnips, cranberry sauce or pickles, and pie or puddings.—Wednesday, remains of yesterday's meat warmed up in the gravy, squash, turnips, potatoes, pickles or sauce, and pie or pudding. Thursday, soup made of the bone and remnants of beef or fresh pork, and bread pudding.—Friday, either veal cutlets, tripe, sausages or steak, with boiled rice or rye mush.—Saturday, salt fish, boiled carrots and beets, potatoes, drawn butter and pork,

with seraps, pickles, and boiled apple pudding.—Sunday, baked beans and Indian pudding.

"For another week's course, as dinner is the principal meal, say:—Monday, boiled corned beef, potatoes, squash, cabbage, turnips, carrots, beets, and baked rice pudding.—Tuesday, cold corned beef, with yesterday's vegetables warmed over, apple pie. Bread, butter and potatoes are of course requisite at every dinner.—Wednesday, a chowder, or fresh fish in some form, mince, apple or squash pie.—Thursday, boil a leg of mutton, or cut it into steaks and broil; serve with drawn butter or caper sauce; potatoes, squash and turnips, and pudding. Friday, make a soup of the remnants of mutton, having saved the water in which it was boiled; or chop the remnants fine and warm up in some of the broth, adding pepper, salt and butter: toast slices of bread and spread this hash upon it, break eggs into hot water, and when cooked skim them out, and lay upon the hash; this is very nice. Pie for dessert.—Saturday, ham and fried eggs, broiled steak or fried pork, fried apples and potatoes. Pie or pudding.—Sunday, steak, stewed or scalloped oysters, cranberry pie, with custard or squash pie.

Supper.—Monday, fresh cold bread, sauce or roasted apples, or preserved canned fruit with sugar sufficient to make it palatable; ginger snaps. Tuesday, hot toasted bread, simple sauce of some kind; plain cake.—Wednesday, toast, sauce, custard, and plain cake.—Thursday, cold fresh biscuit, sauce, cranberry or apple puddings.—Friday, new raised bread, cold tongue or ham, sauce and cake.—Saturday, milk toast, gingerbread, pickled salt fish. All remnants from every meal should be carefully looked after, that nothing be lost. When it is not desirable to have meat at breakfast, this bill of fare will extend over three weeks instead of two, by serving up for a second dinner what would otherwise appear on the breakfast table. By these rules a family may live well and yet inexpensively.

I give several rules for preparing soup, etc., referred to in the above bill of fare:

Dumplings for a soup.—To 1 qt. of flour, add 2 teaspoonfuls of cream of tartar, 1 of soda, salt, milk, just sufficient to wet the flour; drop this by spoonfuls into the pot of boiling soup, after having put in the potatoes, and boil three quarters of an hour, or even an hour. The soup is made by simply boiling any kind of fresh meat either cooked or uncooked, in water for 4 hours, adding three or four onions, and a carrot or two with pared potatoes; season with salt and peppers.

Apple Dumpling.—Butter a tin pail, and line with a paste made as for cream of tartar biscuit, with the addition of a piece of shortening as large as an egg. Mould it a little, but have the dough soft, fill the pail about two thirds full of apples, quartered. Cover with dough over the top, then put on the pail cover, and place the pail in a kettle of water, and boil three hours. Do not let the water rise so high as to boil over into the pail, and have an inverted plate or saucer in the bottom of the kettle in order that the pudding may not burn.

Crumble Griddle Cakes.—Soak bread crumbs in milk (which should be decidedly sour) over night. In the morning mash the bread, and add a little saleratus, salt, and flour, and bake like buckwheat cakes."

Double Heeling Stockings.

Miss S. R. Bowman, Philadelphia Co., Pa., writes to the *American Agriculturist* as follows: "Soldiers very soon walk through the heels of their stockings. Now if the good ladies who knit so much, will only make fine *double heels*, in the following manner, "the boys" will probably foot up a victory in "double quick." Take two balls of yarn, and on the right side knit one stitch with one thread, and the next with the other, and so on across the needle. This alternating makes a loop on the inside, which renders the heel very thick and durable, without making it any wider. On the wrong side, take both threads together, and knit as one, in the usual way."

For other Household Hints see Basket.

Fable of an Ambitious Turtle.

What a foolish turtle! He could not be content with his beautiful swimming pond, his nice bed of rushes, and his dainty dinner of frogs and minnows. He had heard the ducks tell of the wonderful things they saw when sailing through the air, and nothing would satisfy him but enjoying the prospect for himself. So having made friends of a pair of them that built their nest near his home, he engaged them to introduce him to the upper regions in the manner you see in the picture. Cunning fellows they were, real sharpers, as you will presently find. Away they went up, up, until the poor turtle began to grow dizzy and faint, and just as he was immediately over a rocky place, he let go his hold, and down he came upon the stones, where he was dashed into a hundred pieces, and the ducks had a grand feast picking his bones. The writer saw just such a turtle a short time since—only he had two legs, and wore clothing like yours, instead of a hard shell. You would have called him a nice looking young man, and so he was before his nose was painted with brandy. His father was a well-to-do farmer who desired to educate his son to the same profession. But the boy heard lads from the city tell of the fine times they enjoyed there, of the balls, the theaters, and other amusements they attended, and he soon despised his peaceful home, and when of age he took his own way, and came to New York to enjoy the world. He had a few hundred dollars which a relative had left him, and with this he started in business. There were plenty of friendly companions to introduce him to the theater and the gambling house, and they were not long in picking his pockets as clean as the ducks did the bones of the turtle; and when we saw him he was seeking to borrow money with which to return home. Poor fellow, let us hope that his speedy fall shook the nonsense out of him, and prepared him for a new and a right start in life. We have seen old turtles sell their farms to buy a patent right or a flourishing store, of some smooth tongued decoy duck, with which to make their fortunes, but in almost every case they soon came down with a crash. The girls too would do well to think of the ambitious turtle, when tempted to slight the affection of their early friends, for the attention of some spruce young fop from town; if they once fall, they may scarcely hope ever to recover even their former place.

More Nice than Scientific.

A gentleman much interested in botanical matters recently directed one of the clerks at his place of business to copy a list of names for him. On looking over what had been written, he was surprised to find the word "Large-nonion." On pointing out to the young man that an error had been made, he was informed in all sincerity that it was not really incorrect, but only an improvement on the original. The word was *Bignonia*, but as *big* was rather a slang term, he had altered it to *large*, which meant the same thing, and was much more elegant!

Alexander Dumas and Mushrooms.

Once while traveling toward Lake Constance, Alexander Dumas, the noted French writer, was compelled by a storm to stop at a small hotel in Vadutry. He did not understand the language of the place, but managed to ask

for eggs, cutlets, and potatoes, none of which were to be had. Remembering that the mushrooms of that country were in very high repute, he attempted to ask for a dish of them, but his language here failed him. As a last resort, he snatched a pencil, and paper, and drew what he thought to be a good representation of them. "Oh, yes, yes," said the woman, and she at once started out. In five minutes she re-appeared, bringing Dumas an *open umbrella!* A second look at his sketch convinced him that she had brought what his picture most nearly resembled. Perhaps the rain then falling may have helped her imagination. (Try your skill in sketching a mushroom.)

Fable of an Aristocratic Beetle.

Our artist, who dreams with his eyes wide open, and who sketches the marvelous things he observes when in that state, says that this is a correct representation of a *hum-bug* he found among the insects. To common eyes he looked like only a fat brown beetle; but being the proprietor of a large manure heap, he was accounted very rich, and was therefore highly honored by his fellow insects. He disdained to employ his own legs for crawling, and the humble grasshopper was only too glad to earn a livelihood by wheeling his carriage, and his neighbors took off their hats and made their obeisance as he passed. We presume the artist had been rudely treated by some purse-proud and ignorant *nobody*, and his imagination was so much disturbed, that he fancied for a moment that other creatures besides men were capable of such meanness. We will leave you to make out the rest of the story, and to discover the moral. There is more in this picture, than appears at first sight. Examine it thoughtfully, and let us hear what instruction you find in it.

Impertinence Punished.

A correspondent writes to the *Agriculturist* from Wayne Co., N. Y.: "Near our village lives a young Miss just blooming into womanhood, who attracts much attention by her beauty. She is a merry hearted, but sensible girl, and apparently in nowise spoiled by the many compliments she receives. Recently she greatly enjoyed the discomfiture of a young man who rather impertinently attempted to introduce himself. He had recently come from the City, and dressed in the height of fashion, was riding with a companion when he caught sight of Miss L., who was just drawing a kettle of water from a spring near the house. He exclaimed, "what a charming creature! I must make an acquaintance," and forthwith he stepped from his carriage, and with a very stylish bow, requested "the privilege of drinking water drawn by such fair hands." She started to bring a tumbler, but he insisted on drinking from the kettle, and raised it to his lips. Just then a mischievous pet sheep belonging to Miss L. came frisking around the corner behind the stranger, and without any warning, with a powerful butt sent him sprawling headforemost into the spring, kettle and all! He was not injured, but the starch was thoroughly taken out of him, as well as from his shirt bosom, and he lost no time in scrambling back to his carriage and hurrying away from the sound of Miss L's laughter."

A Formidable Weapon.

The New-Haven Palladium narrates the following: "Two drummer boys of the Tenth Connecticut Volunteers, while off duty, when Gillmore was pounding Fort Wagner, determined to discover the effect made upon the fort. They borrowed an opera glass, and went out a distance from camp to obtain a favorable site to witness operations. They had proceeded about three-quarters of a mile, when they came suddenly upon a burly rebel, who, upon sight of them, snapped his gun at them, which did not explode, the piece not being capped. One of the boys at that moment thrusting the glass into the case which hung by his side, the rebel thought he was drawing a revolver, and immediately threw down his gun, crying out "I surrender." The boys immediately sprang forward, seized his gun, and at a "charge bayonet" drove the big fellow into camp. When he discovered that the only appearance of a weapon in the boys' possession was an

opera glass, he was much incensed, declaring he could not be held as a prisoner of war; but, of course, being fairly caught, his protestations were of no avail.

The Dog and the Kitten.

An instance of the intelligence of dogs is thus related by a writer in the London Agricultural Gazette, who vouches for its truth. The dog, a female, had a family, which were all taken away and drowned. Shortly afterward, three cats on the premises each had a litter of kittens, and these were all thrown into the water by a servant; but as he was returning, he was met by the dog, carrying in her mouth one of the kittens which she had rescued. The servant tried to take it from her, but she escaped, and for a time no one could make out where she had put it. Some hours later, at night, a mewing was heard in the far end of a large stable, and there in the corner were the three cats disputing which had the right to care for the little one. The dog sat by, looking on, and from time to time taking the kitten in her paws, and licking, and warming it.

Not Exactly a Plaything.

"O what a nice plaything!" our young friends will exclaim, on looking at the little girl in the picture seated at a tiny sewing machine. But it represents something more than a child and a toy. The "little girl" as you would call her, is Mrs. Charles S. Stratton, (Tom Thumb's wife,) and it is a very good likeness of the petite lady. The little sewing machine is a perfect one in all its parts, and can be used by its mistress to make up her family clothing. It was manufactured by Wheeler & Wilson, and is a most beautiful specimen of art. It is only 20 inches high, and 15 inches deep, cased with richly carved rosewood, inlaid with beautiful ornaments of pearl and gold, and lined with satin wood. The panels are painted with tasteful devices, fairies, cherubs, etc. On one side is a likeness of the bride arrayed as the "Goddess of Liberty," and on the other is the General, as "Young America." There is also a representation of the little bridal party with their attendants. Those who visit New York soon, may see it at the sales-room No. 505 Broadway.

How to Improve in "Composition."

To write a good "Composition" is an accomplishment usually requiring much study and long practice. Study is necessary to furnish the writer with thoughts, and practice to enable him to express them clearly, forcibly, and with elegance. One of the best aids in acquiring a good style is to read the production of some standard author, remember his thoughts, and then try to write them out. The effort should be, not to remember and repeat the language of the copy, but to express the ideas. Then compare what is written with the model, and observe the difference in arrangement, choice of words, and structure of sentences, and notice in what particulars the original excels. The most accomplished authors have practised this method and found it an excellent means of improving their own modes of expression. This suggestion has particular reference to the manner of expressing one's thoughts, which is important, as the reader is more easily interested by that which is stated with clearness and grace. But the first essential is to have something to say. A topic in which the writer himself is much interested, will usually furnish matter interesting to others; therefore the author should endeavor to be full of his subject; his success will be easier if the theme comes within the experience or observation of those for whom he writes.

Pronouncing Either and Neither.

"Vermont Boy," writes: "Will our Editor of the *Agriculturist* please tell us how to pronounce the words *either* and *neither*? We have in this town two learned ministers, one of whom says 'ee-ther,' and 'nee-ther,' and the other says 'i-ther,' and 'ni-ther.' Which is right?" *Answer.*—The general custom in this country is in favor of *ee-ther* and *nee-ther*, and the standard dictionaries give this pronunciation the preference. We noticed that in England, Scotland, and the North of Ireland, they generally say *i-ther* and *ni-ther*, while in Dublin, the common people say *a-ther* and *na-ther*. Where universal good custom does not forbid, it is best to make our language as regular as possible by following analogy, and this favors *ee-ther* and *nee-ther*, as in ceiling, conceive, deceive, receive, seize, and in most other words where the *ei* is not followed by *gh* or the liquids, *l* and *n*. In these words *ei* has the sound of *a*, as in eight, neigh, sleigh, weigh, or fein, rein, skein, veil, vein. Analogy would even indicate the Hibernian pronunciation of 'a-ther' and 'na-

ther,' in preference to *i-ther* and *ni-ther*. To preserve the analogy, we would prefer the foreign pronunciation of *hight*, like *hate*, this being the only word we now recall, in which *ei* has not the sound of *e* or *a*, in this country.

Writing in "Cypher."

This is a method of sending communications in such a form that they can only be read by those having the key. In a former number of the *American Agriculturist* we partly explained this to our young readers. Here is a dispatch in cypher of historic interest, which was found in the coat collar of a scout intercepted by the Union soldiers, on June 30, 1863, during the memorable siege of Vicksburg, four days before the surrender.

"Ngsgv Icp Rcoezgpmvp Amwp ocuqceg gd vfg 46 vf kq tceektgb K ygnj tcklhtag amw er vfg gylkeur omocpr Jnub hyur er ejl qbfq vgnj K teca amw K ygnj fgxfce ow hntaga elf crvyei Ipclyq tgfiv elf nehr cr 6' e k qd vfg qj qd lsnw—Lmuerr Lmjrlqr, Icp Emo—Lyeiump Oguq Lspe 58vf 3681."

This was deciphered by Michael Mason of Waterhouse's Chicago Battery. The key to the cypher is, that instead of the proper letter, the second one below it in the alphabet is used for the first, third, fifth, seventh, and ninth letter of each word, as *c* for *a*, *d* for *b*, *e* for *c*, and so on. But for the second, fourth, sixth, and eighth letter of each word, the second one above is used, as *h* for *j*, *i* for *k*, *q* for *s*, etc. The same rule is followed with figures. At the end of the alphabet, suppose another alphabet to follow as *v w x y z a b c d*; and so of figures, *8 9 0 1 2 3*. With this key, the above dispatch (which is printed wrongly in all the papers we have seen) reads:

"LIEUT. GEN. PEMBERTON: Your message of the 28th is received. I will reinforce you at the earliest moment. Hold fast at all odds till I reach you. I will divide my forces and attack Grant's right and left at 4 A. M. of the 7th of July. JOSEPH JOHNSTON, Gen. Com. Jackson, Miss., June 30th, 1863."

Gen. Johnston has doubtless adapted a new cypher ere this. Our young readers can construct others for amusement among themselves, though it will not pay to spend a great deal of time over this when you can be better employed in reading. Our only object is to make you familiar with what is a very important aid to government officers, especially military men. Here is an example on a different plan, which you can read if you get the key:

Concealed Portraits.

Many of our young readers, and not a few of the older ones, were much amused in making out the portraits of the Bonaparte Family, contained in the picture of a bouquet, published in the *Agriculturist* some months since. We present now a somewhat different device, in which are four portraits—the French King Louis XVI, his

wife, and their two children. At first it may be a little difficult to observe them, but when once discovered, it will be almost impossible to look at the picture without seeing them. It is related that this and similar methods of preserving the likenesses of distinguished persons have been extensively practised in France, when the ruling powers have forbidden the publishing of portraits of those they considered their enemies. We have seen representations of posts turned in a lathe in such a way that the shadow falling from them showed the desired profile.

New Puzzles to be Answered.

Fig. 1.

No. 56. Puzzle Picture.—(Fig. 1.) How does the boy in the picture represent a musician?

Fig. 2.

No. 57. Illustrated Rebus. (Fig. 2.)—A well known Scripture quotation, very nearly in the words of the text.

No. 58. Miscellaneous Questions.—What relation is the door mat to the scraper? Which is the largest room in the world? What word of three syllables includes all the letters of the English language?

Answers to Problems and Puzzles.

No. 51. Mathematical Problem.—"A, B, and C, with their wives, P, Q, R, went to market to buy pigs. Each man and each woman bought as many as they gave shillings for each pig. A bought 23 pigs more than Q; B bought 11 more than P; also each man laid out 63 shillings more than his wife. Which two persons were man and wife?" This problem excites so much interest that we give the best solution received—furnished by "W. C., Jefferson Co., Ind.: Each person bought as many pigs as he or she paid shillings apiece for them, therefore the whole number of shillings that each paid is a square number. And as each man paid 63 shillings more than his wife, therefore 63 is the difference between the squares denoting what each man and his wife paid. But "the

difference between two squares is equal to the product of the sum and difference" of the two numbers from which the squares were formed. Then 63 is the product of two factors, one of which is the sum, and the other the difference of two numbers. (And the nature of the problem implies whole numbers.) Then 63 is to be resolved into two factors, one denoting the sum and the other the difference of two numbers. And first, A bought 23 pigs more than Q. Then the sum of the numbers that A and his wife bought is evidently greater than 23, and it must also be a factor of 63. It is also plain that no number greater than 23 can be a factor of 63, except the number 63 itself. Therefore 63 is one factor (the sum of A's and wife's pigs), and 1 must be the other factor (the difference of A's and wife's pigs). And half the amount of the sum (63) and the difference (1), is 32 the greater of the two numbers, which is A's number of pigs. And half the difference between the sum (63) and the difference (1), is 31, A's wife's number of pigs, being the less number of the two sought. Second: B bought 11 more than P. Then it is evident that B and wife bought more than 11, and the sum of the numbers that they bought must be a factor of 63. The only number greater than 11 which is also a factor of 63, is 21 (except 63 which has already been disposed of). Therefore 21 is one factor (the sum of B's and wife's pigs), and 3 must be the other factor, (the difference of B's and wife's pigs). And as before (21+3)÷2=12, the greater number which is B's number of pigs. And (21-3)÷2=9 the less number, which is B's wife's number of pigs. Third, the only remaining factors of 63 are 7 and 9. And (9+7)÷2=8, which is C's number of pigs, and (9-7)÷2=1, which is C's wife's number. Fourth, A bought 23 more than Q; but A bought 32, therefore Q bought 9, and we have seen that B's wife bought 9; there

fore Q. is B's wife. And as B. bought 11 more than P., therefore P. bought 1, and it has been shown that C's wife bought 1; therefore P. is C's wife. Finally, R., the only woman left, with her 31 pigs, must belong to A.

No. 53. *Mathematical Problem*, (October No., page 311.) *Answer*.—The land cost \$2,500; the fence, \$1,309; the sheep \$3,927. No. 54. *Illustrated Rebus* (Oct. No., page 311.)—Awl men (shoemakers) th in K awl men mortal (dead man) butt hems elvers; or "all men think all men mortal but themselves" The following have sent in correct answers; the numbers indicate the problems, etc., answered by each. H. S. Loper, 49; Maine Correspondent, 51; Wm. Holmes, 51; J. M. Cole, 51; Mary Hoge, 51; "Nauticus," 49; "W. C.," 51; E. C. Modewell, 51; "J. H. B., Jr.," 51; J. Oltman, 51; J. Biddle, 53.

PREMIUMS for 1864.

Or Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all—No Competition.)

Owing to the greatly increased cost of everything connected with publishing, and our determination not to raise the subscription price, and not to diminish the intrinsic value of the paper, but rather to improve it, we had expected to give no premiums hereafter, excepting the Great Strawberry which will be a premium to every subscriber, and ought to be enough to secure as many subscribers as could be desired. But the previous plan has worked well, and many of those who have obtained premiums hitherto, express a strong desire to have an opportunity to get some of the higher premium articles. After looking the ground all over, and making a careful estimate, we have decided to offer one general list, as named below. Any one desiring to do so, can go to work at once, and perhaps this very month get names enough for a good premium. All names sent in now, get the great strawberry plants and the extra number. Note that five cents extra are needed when the "Agriculturist Strawberry" plants are desired, if to go by mail. This will, of course, be paid by the subscribers themselves.

The names (with money for each,) can be sent in as fast as gathered, so that the subscribers can begin to receive their papers. The premium will be paid to any one as soon as his list is completed. *But, let it be distinctly noted, we can reckon for premiums only those names which are marked as for Premiums, when they are sent in.* Hereafter all the separate names thus sent and marked as for premiums, will be at once numbered in a special book, with the name of the sender, so that we can immediately turn to any canvasser's list, and see when it is full.

Premium clubs need not necessarily be all at one Post-Office. Each list ought to contain a fair proportion of new names, for it is to bring the paper before new subscribers, that the premiums are in part intended.

Table of Premiums for 1864.

Names of Premium Articles.	Price of Premiums.	Names at \$1 each.	Names at 50 cts each.
GOOD BOOKS.—See terms below *			
A—American Cyclopaedia (Appleton's New)	\$56 00	130	250
B—Best Family Clothes Wringer	\$7 00	19	45
C—Nonpareil Washing Machine	\$16 00	40	90
D—Sewing Machine, (Wheeler & Wilson)	\$45 00	95	195
E—Sewing Machine, (Wilcox & Gibbs)	\$40 00	82	185
F—Woodruff's Mercurial Barometer	\$8 00	20	65
G—Woodruff's Mercurial Barometer	\$10 00	30	94
H—The Aquarius	\$10 00	25	67
I—Five Octave Melodeon (best)	\$80 00	170	340
J—Four Octave Melodeon (best)	\$55 00	120	234
K—Seven back Volumes Agriculturist	\$5 00	38	84
L—Six do do do do	\$4 44	25	58
M—Five do do do do	\$2 77	20	49
N—Four do do do do	\$4 96	19	42
O—Three do do do do	\$5 72	16	38
P—Two do do do do	\$2 45	13	24
Q—One do do do do	\$2 24	10	15
R—Jacob's Portfolio Paper File	\$1 50	3	17
S—Osborn & Hodgkinson's Paints	\$1 50	3	17
T—Premium Cylinder Plow	\$10 00	33	78
U—Eagle Plow No. 20	\$9 25	30	69
V—Hay and Straw Cutter (best)	\$9 00	28	65
W—Steel-tooth Cultivator (best)	\$4 50	25	58
X—Family Lard and Wine Press	\$4 00	24	54

No charge is made for packing or boxing any of the articles in this Premium List. The books and the Premiums K, to S, inclusive, are DELIVERED to any part of the United States and Territories, free of all charges. The other articles cost the recipient only the freight after leaving the manufactory of each. *Every article is new and of the very best make.*

N. B.—Every article offered, is a good one—nothing second-hand or of poor make, or quality, or kind. We intend in all cases to deal fairly with every one, and esteem as special friends those who labor to promote the interests and circulation of this journal.

This list may perhaps be altered or amended from time to time, if circumstances or change of prices, etc., require,

but all names sent in during any month, will be reckoned at the premium rates announced for that month.

Canvassers need not choose any particular premium until they get all the names they can. To avoid confusion, please send in the exact amount with each list of names. In special cases, the whole sum for a premium list may be forwarded, and the premium be received at once—the names to be sent in afterward.

Descriptive Notes on the Premiums.

* **Books.**—Any person sending 20 or more subscribers, may select from our book list (page 351) to the amount of 10 cents for each name sent in at the club price of 80 cents, or to the amount of 30 cents for each name at \$1. (No books sent for less than 20 names). The premium books will be delivered anywhere in the United States, or to the border of the British Provinces, free of all cost, by mail or express. Many Farmers' Clubs have, by means of this premium, obtained a good library.

A—Appleton's New American Cyclopaedia.—This magnificent work is now completed, and ready for immediate delivery. It consists of 16 heavy volumes, averaging 800 large two column pages, or in the whole work, 12,804 pages! (The books fill up over a yard of shelf-room.) *It is in reality a complete library of itself, embracing full information upon every topic of human knowledge, alphabetically arranged for convenient reference. The subjects discussed number over twenty-five thousand!* It is hardly possible to name anything upon which pretty full information may not be readily found in the Cyclopaedia. Many who can not purchase the work may be able to obtain it through our Premium offer. It is worth a year's effort in raising subscribers, though not a few may make up a club of 130 names in a brief time.

B—Best Clothes-Wringers.—This is a most excellent Household Implement, which should be in every family. It can be set upon any form of tub, and by turning with the right hand and picking up the garments with the left, they are pressed rapidly and easily between two elastic rollers, and drop out into a basket quite as free from water as they can be wrung by the hardest twisting by hand. Every lady knows that hand wringing is really harder upon the arms and shoulders than even the washing; while the twisting stretches the fibers with lever power, and hastens the wearing out. All this is avoided by the Wringer, which is in truth a *strength-saver*, and a *clothes-saver*. We have had one of the first imperfectly made instruments in weekly use for nearly four years, and it is as good as ever, while it has paid for itself many times over. A child can with this readily wring out a tub full of clothes. Our Premium Wringers are of the family size, and of the best manufacture, and are provided with cogs, and with springs, so that they will wring equally well any article from a blanket to a baby's stocking. The Wringer weighs only 15 lbs., occupies but a small space, and can be carried by hand, or sent by express, or as freight to any point, and is ready for instant use on removing the light packing box.

C—Nonpareil Washing Machine.—The best recommendation we can give of this, is, that while we have tried fifteen or twenty kinds, this is the only one that our "help" continue to use without being required to do so. It acts somewhat like the old "fulling mill;" the clothes are put into the hot water, and beat by two pounders which constantly turn them over. The beaters are moved alternately by a crank, provided with balance wheel which adjusts the force required so as to make the turning easy. Take it all in all, the Nonpareil is the best Washing Machine we have found. If we could find a better one, we should put it in our list, for anything that helps to reduce the hard work of washing day, is a godsend. The machine can go as freight, or by express to any part of the country, and we believe will give better satisfaction than any other yet brought out.

D—E—Sewing Machines.—We need not enlarge upon the benefits of Sewing Machines. They are doing more than all else to save the lives and health of females. It is no exaggeration to say that a woman can in a day do *ten times* as much ordinary sewing with a machine, as she can do by hand. We know many ladies who formerly employed a seamstress several weeks every year, but who now do all their family sewing, with less confinement and wear than when the common needle was their only resort. The interest on a fifty dollar Machine is only \$3 to \$4 a year, which is a small consideration compared to its advantages. Five hundred families ought to be supplied through our premium list *this year*. At least 80 to 100 copies of the *Agriculturist* ought to be taken in every town, and would be if some enterprising man or woman would go round and gather them. Two or three ladies might join their efforts, and get a machine for use between them. We offer two kinds of Machines, both varieties of which we have had in use for several years, and with great satisfaction. They are both supplied with the Hemmer, and are sent out with full instructions for use.—The **Wheeler & Wilson Machine**, we have used during five years, and can bear full testimony in its favor. More of these machines are sold and used, we believe, than of all the other good kinds together, which is a strong proof of the satisfaction they give.—This sews with a double thread, both sides of the fabric showing the same stitch.—The **Wilcox & Gibbs Machine**, we have used for over three years, and for most kinds of sewing it is excellent. It is very simple in its operation and can be worked by those who have the smallest amount of mechanical skill. It can be used for most kinds of sewing, and may well be adopted generally, at least where the higher priced machines can not be afforded. We know many who prefer this to any other.—For every kind of sewing, especially where the same stitch is required on both sides, we prefer the Wheeler & Wilson.

F—G—Woodruff Mercurial Barometer.—This is conceded to be the best and cheapest instrument for general use, which is now offered to the public. The peculiar

form of mercury cup invented by Mr. Woodruff, renders the instrument far more portable than anything previously made. The *safe delivery* of every instrument given by us as a premium, is warranted by the manufacturer (Charles Wilder, Peterboro, N. H.), when to be sent within 1,500 miles. The instruments are beautifully made, are about 3 feet long, and are sent direct from the factory, with no expense save the express charges which vary from 50 cts. to \$1.50, according to the distance. We offer two forms which differ mainly in the style of case, both being supplied with *Thermometer* and *Vernier*. The \$12 form is of course more ornamental, and the more desirable instrument, though either of them is highly valuable. A barometer is to farmers or others on land, what it is to sailors at sea—an indicator of the weather to be looked for. There are many times every year when the indications of the barometer in regard to the weather, will often be of more value than its whole price, while the interest on its cost would be less than half a dollar a year. The *habit* of observation, and of scientific study cultivated in a family of children where a Barometer is used, is a valuable consideration.

H—The Aquarius.—This is an excellent little portable force-pump, useful in many ways. One can take this instrument in his hand with a pail of water, and throw a considerable stream to any point where a fire may be breaking out, and do more to quench it, than he could with a dozen pailfuls dashed on, even if the fire could be reached. We have thrown water from the ground up against the third story windows of a house. The Aquarius is very useful for watering gardens, for washing windows, carriages, etc., etc. It is provided with rubber suction pipe, to draw water from a pail, tub or bucket, and an ejection pipe having both a nozzle for throwing a stream, and a rose or sprinkler. It has also an air chamber for giving a constant stream. It is a handy instrument, for every household, aside from its benefit as a fire engine with which many an incipient fire has been subdued.

I—J—Melodeons.—None need to be told of the pleasure given by a good Melodeon in a household, or of its utility in the Week Day and Sabbath School Room, and the Church. "Musical charms to soothe even a savage breast," and we hesitate not to say that a benign influence is exerted upon every house and school room where a Melodeon or other good musical instrument is found.—We offer two sizes in our list above, and those of a different price may be selected for a proportionate number of subscribers. (For sizes, style, prices, etc., send a stamp to George A. Prince & Co., Buffalo, N. Y., and get one of their illustrated descriptive Catalogues, which will be sent free.) We have used one of these Melodeons during four years past, and it continues to give the highest satisfaction. It has not been tuned or otherwise repaired in all that time. The premium instruments will be shipped direct from the manufacturers at Buffalo, ready boxed. They can go by railroad, steamboat, express or otherwise, as desired by the recipient. *It will be an easy matter for Churches, and both Week Day and Sunday Schools to unite their efforts and secure an instrument for the public use.*—Many have done so already.

K—Q—Seven Volumes of the Agriculturist.—Here is a whole *Agricultural, Horticultural, and Household Library*, embracing also a large amount of interesting reading for Children and Youth, and thousands of instructive and pleasing engravings. Each volume contains more printed matter than half a dozen dollar books of the usual size. There are in each volume from one to two thousand articles and condensed items, among which every reader will find something useful to himself and family. We send them post-paid (as in the above table,) in new clean numbers, printed from stereotype plates as needed. The last number of each volume contains an index to the whole volume. (Any person preferring them bound, can receive them in this form, neatly done, at an expense of 65 cents per volume, for the cost of binding, and extra postage required when mailed in this form—or if called for at the office, or sent by express, or otherwise, if not to be pre-paid, at a cost of only 25 cents per volume.) Let every one selecting this premium be sure to name what volumes are desired, or how many of each, as duplicates of any number can be chosen if preferred.—We can only supply from volume 16 to volume 22 inclusive. The previous volumes are not stereotyped.

R—Best File for the Agriculturist.—Jacob's Portfolio file, made just to fit the *Agriculturist*, with the name of the paper gilded on, is exceedingly convenient. It is a neatly embossed or stamped cover, made so that each successive number of the paper can be inserted in a minute, when it is strongly held in. The numbers thus fastened together are as convenient as a bound book. When one volume is completed, it can be removed and stitched together, and the numbers of a new volume be inserted. A single cover will answer for a dozen or twenty successive years. It is without doubt the most perfect paper file yet made. It is sent post-paid, as above.

S—Water Color Paints.—Those offered (Osborne & Hodgkinson's) are the best of American Manufacture, and though not so fine for artist's work, as some of the imported (which now sell at six times the price), they answer very well for common sketching, particularly by children and beginners. They are especially useful to children, as their use tends to develop a taste for form and color, and skill in the use of the pencil. We send them post-paid, in a neat mahogany case containing 24 small cakes of assorted colors, with brushes, etc.

T—U—Premium Plows.—The two named in the table above (*Cylinder* and *Eagle No. 24*) are two of the best farm plows in use, and will doubtless give ample satisfaction to any one securing them as premiums. We have not space for a particular description. The *Eagle Plow* is well-known. The working of the *Cylinder Plow*, and other items concerning it are described on page 136 of Volume XX, (May 1861).

V—W—Hay and Straw Cutters—Steel-toothed Cultivators.—These implements are of first importance to all farmers, some of whom may find it most convenient to secure them through our premium list. We send the best implements we know of at the prices named.

The Markets.

The foregoing tables present a very carefully prepared comparison of the receipts and sales of Breadstuffs here, during the past and preceding months. The business of the past month has been quite heavy, in the line of reported sales, but as these are largely on speculation, the reduction of the available supplies is not very serious. The principal speculative purchases have been made on Western account, especially of Wheat and Corn. Western dealers have been endeavoring to get complete control of the market, but have been only partially successful, and they are now becoming apprehensive of a reaction that may prove disastrous to many of them. Inflation of prices by any illegitimate means is always of very temporary duration, and is ever sure of being followed by extreme depression. As will be seen on com-

paring the annexed list of prices, this day and a month ago, every article in the produce line is much dearer to-day. The rise has resulted less from legitimate causes than from the action of speculators. It has checked the demand from regular buyers, both for home use and for shipment. Stocks, instead of diminishing, have been accumulating, and at the close most holders appear to be eager to realize. A serious falling off in the prices is momentarily expected, though the rapid rise in, and prevailing high quotations for gold and foreign exchange, serve for the time being as a prop to the market... Cotton and wool have been in brisk demand, and have rapidly advanced, the market closing very firmly with a lively inquiry, especially for all kinds of Wool wanted by manufacturers.... Tobacco has been more sought after and has been tending upward... Hay, Hops, and Seeds are dearer, with more doing.... In most other agricultural products, transactions have been fair. The Price table shows present prices, and changes since our last quotations.

N. Y. Live Stock Markets.—The Cattle markets have been very largely supplied during the past month, the receipts averaging 6,238 per week, while the weekly average for all of 1862, was only 4532. For the week ending Sept. 22, 5,775 heaves were received and sold at last month's prices. For the week ending Sept. 29th, the supply was the largest ever received, amounting to 7,051 head. They were all disposed of, some of them to graziers, at an average decline of 1/2 c. per lb. For the week ending Oct. 6th, 6,581 cattle were received, and a further decline of 1/2 c. was the result, with 200 left unsold. At the last general market, Oct. 13th, the weekly supply was 5,647, and all were sold at 1/2 c. advance, a few of the best at 1 1/2 c. per lb. for the estimated dressed weight; good steers, 10c.; ordinary cattle, 8c.; and the poorer sorts, of which there was a large number, at 6c. @ 7c. The average of all sales was about 8 1/2 c.

Milk Cows.—The receipts have averaged 112 per week, and they are now selling rather better than last month, a few fancy ones as high as \$70 each, but most at \$40 @ \$50, which is the price of good milkers.

Veal Calves.—Average receipts, 775 per week. They are now selling readily at 7c. @ 7 1/2 c. per lb. live weight, for fat calves, and 6c. for fair veals.

Sheep and Lambs.—The receipts have averaged 15,198 per week. There has been considerable inquiry for store sheep to winter over, and butchers have bought freely, paying pretty uniformly, 5 1/2 @ 5 3/4 c. per lb., live weight, for fat sheep, and about 7c. for lambs. In lots, as they arrive from the West, sheep and lambs average \$4.25 @ \$4.50 per head. The advance in wool enhances the value of sheep, and farmers are very generally increasing their flocks.

Live Hogs.—Receipts increase as the weather grows cooler. Weekly average for the past month, 20,700, or double the number for the previous month. Prices are unchanged, ruling at 5 1/2 c. @ 5 3/4 c. per lb., live weight, for fair to prime corn-fed hogs; and 4c. @ 5 1/2 c. for poor mast and fat still-fed hogs. Market brisk.

The Weather.—For a month past has been mild and pleasant for the season, with comparatively little rain, and but one or two light frosts, hardly enough to injure vegetation in this vicinity. Timely rains after our last report, revived the drying pastures somewhat, and helped out the buckwheat crop, and was of material help to growing turnips. It has, however, been much too dry for strawberry plants, and few runners have been made without artificial watering. — OUR DAILY NOTES, condensed, read: — September 18 and 19, rain—20, showery—21 to 24, clear, cool, with the first frost here on the morning of the 23d—25, light rain—26 to 30, clear and fine. — October 1, clear and fine—2, cloudy, rain at night—3, 4, cloudy—5 to 7, clear, cool, frost morning of 8th—8, cloudy A. M., light rain P. M.—9, clear, fine—10, cloudy—11 to 15, clear, fine, rather dry—16, rain.

Rain Fall for September, 1.05 inches, making a very dry month. The Barometer has ranged from 29.35 to 30.40, making a variation of nearly 1 inch.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit). — r indicates rain—s, snow.]

To Sunday School Teachers and Others.

The Book of "Lessons for every Sunday in the Year," can be obtained at the American Agriculturist Office in large or small quantities, at the uniform price of 10 cents per copy. If to go by mail, the postage to be pre-paid, is 3 cents each copy in packages of ten or more. The postage being rated by the 4 ounces, under the new law, the price for less than ten pre-paid by mail is:

1 copy, 14 cents.	4 copies, 52 cents.	7 copies, 90 cents.
2 copies, 28 cents.	5 copies, 66 cents.	8 copies, 104 cents.
3 copies, 42 cents.	6 copies, 80 cents.	9 copies, 118 cents.

THE SECOND SERIES of the above book will be published early in November. It will be of the same size and price as the first Series, and is a most valuable book.

Business Notices.

87 Eighty Cents per Line of space.

BEST AND CHEAPEST.—"Doty's New-York Clothes-Washer" is warranted to clean the bulk of eight shirts in five minutes, and not injure the finest fabric. See advertisement.

PREPARE FOR THE HOLIDAYS!

Booksellers, Fancy Goods Dealers, and the Public, will please remember that there is no other Gift which compares with the CRAIG MICROSCOPE and MOUNTED OBJECTS, being an endless source of amusement and instruction. Over 200 dozen Microscopes and 700 dozen Objects have been sold within a year by the Boston Agent alone. This Microscope, in brass, is mailed, postage paid, for \$2 25; or with six beautiful mounted objects for \$3; or with 24 objects for \$5. In hard rubber, for 50 cents, in addition to the above price. A liberal discount to the trade. Address,
HENRY CRAIG, 335 Broadway, N. Y.

Lands—To All Wanting Farms.

Large and thriving settlement of Vineland, mild climate, 30 miles south of Philadelphia, by railroad; rich soil; fine crops; twenty-acre tracts, at from \$15 to \$20 per acre; payable within four years. Good business openings; good society. Hundreds are settling and making improvements. Apply to CHAS. K. LANDIS, Postmaster, Vineland, Cumberland County, N. J. Letters answered. Papers containing full information sent free.

Fifty cents per line of space for each insertion.
One whole column (145 lines), or more, \$60 per column.
87 Business Notices, Eighty cents per line of space.

IMPORTANT SALE

OF

VALUABLE HORSES.

The most valuable collection of Trotting Stock ever offered to breeders, will be sold at PUBLIC AUCTION on Thursday, Nov. 19th, 1863, at the farm of S. R. Bowne, Flushing, L. I. (Flushing is distant 8 miles from New-York City, conveniently reached by Railroad, from James Slip and 34th-st. Ferries, ten times a day.)

The collection will number about fifty, mostly colts, among which are a large number of **Toronto Chiefs**, ages varying from foals up to four year olds. Also all the brood mares in foal by **Toronto Chief**.

Among the brood mares offered will be the great trotting mare **SONTAG**. This mare is a grey, 16 hands high, of a pure Messenger stock, and among her feats upon the turf, she beat **Flora Temple** in a race, making the fastest time on record with wagon and driver weighing 300 pounds. **Sontag** was purchased for breeding at a cost of \$1,700, and has never failed to produce a colt every year. Her first two colts were sold to breeders for \$4,500. She is now in foal by **Toronto Chief**. Three of her colts by **Toronto Chief** will also be offered, two **Fillies**, and one fine bay **Stallion**, 16 hands high, with promise of great speed. This last is without doubt the most valuable stock horse in the country; will be four years old November 15th, and has never been bred.

Toronto Chief will also be sold. He is a very dark bay, no white, sixteen hands high, of great power, weighs upwards of 1200 pounds, and is nearly thoroughbred, being a cross of the noted Royal George Stallion and a blood mare. His present owner purchased him solely for breeding; he has never appeared in public except as shown at the county fair on the Fashion Track, in ordinary condition, yet he there, without training, showed the extraordinary time of 1:12 to the half mile. This horse is entirely sound, and an offer at private sale of \$14000 has been refused for him.

The famous untrained mare known as the **Colt of Euraka** is a large bay, weighing about 1,100 pounds, height 15.3. Before she came from the hands of a farmer, she trotted upon a rough track, a mile in 2:30, since which time she has not changed hands, nor been shown in public, but has gained steadily, and her present owner considers her second in value to none in the United States.

The sale will be positive and without reservation.

P. S.—Also a fine **SHORT HORN BULL** bred by Samuel Thorne, Esq. of Dutchess Co. N. Y.—got by the second Duke of Thorndale out of **Flour de Lis**—a roan three years old last Spring, very large. For a full history of this bull see **American Herd Book**.

Catalogues of the above stock furnished on application to
JAS. M. MILLER, 28 Pine-st., New-York.

WANTED—A SITUATION AS FARMER. OR to assist a gentleman in farming, by an Englishman, capable of taking the charge of a large stock farm, having experience in buying and marketing stock—knowledge of crops, steam machinery, Dairy Farm accounts, etc. Address "S. S." care of J. MACKAY, 221 Pearl-st., New-York City.

[CIRCULAR.]

IMPORTANT INFORMATION.

U. S. 5-20's

THE SECRETARY OF THE TREASURY has decided to continue for a short time the sale of this popular Loan at Par, or until ten days notice is given to the contrary.

The whole amount of the Loan authorized is Five Hundred Millions of Dollars. **Nearly Three Hundred Millions have been already subscribed for and paid into the Treasury**, mostly within the last six months. The balance, (Two Hundred Millions,) is hardly sufficient to furnish the basis for circulating notes for the National Banking Associations now rapidly organizing in all parts of the country.

The sales frequently reach **Two Millions** in a day. It is confidently expected that the sales will still further increase, especially as a large foreign demand (mostly from Germany,) has lately sprung up, which is likely to absorb One or Two Millions, weekly. A very short period only must elapse before this Loan is wholly absorbed, and as it is well known that the Secretary of the Treasury has ample and unfailing resources in the Duties on Imports and Internal Revenues and in the issue of the Interest bearing Legal Tender Treasury Notes; it is almost a certainty that he will not find it necessary, for a long time to come, to seek a market for any other long or permanent Loans, the **Interest and Principal of which are payable in GOLD.**

Prudence and self-interest must force the minds of those contemplating the formation of National Banking Associations, as well as the minds of all who have idle money on their hands, to the prompt conclusion, that they should lose no time in subscribing for this most popular Loan. It will soon be beyond their reach, and advance to a handsome premium, as was the result with the "Seven-Thirty" Loan when it was all sold and could no longer be subscribed for at par.

It is a Six per cent. Loan, the Interest and Principal Payable in Gold, thus yielding Eight to Nine per cent. per annum at the present rate of premium, on coin.

The Government requires all duties on imports to be paid in Coin; these duties have for a long time past amounted to over a Quarter of a Million of Dollars, daily, a sum nearly three times greater than that required in the payment of the interest on all the 5-20's and other permanent Loans. So that it is hoped that the surplus of Coin in the Treasury, at no distant day, will enable the United States to resume specie payments upon all liabilities.

The Loan is called 5-20 from the fact that whilst the Bonds may run for 20 years, yet the Government has the right to pay them off in Gold, at par, at any time after 5 years.

The Interest is paid half-yearly viz., on the first days of November and May.

Subscribers can have Coupon Bonds which are payable to bearer, and are of \$50, \$100, \$500, \$1000; or Registered Bonds of same denominations, and in addition, \$5,000, and \$10,000. For Banking purposes and for investments of Trust-moneys the Registered Bonds are preferable.

These 5-20's can not be taxed by states, cities, towns, or counties, and the Government tax on them is only one-and-a-half per cent., on the amount of income, when the income of the holder exceeds Six Hundred dollars per annum; all other investments, such as income from Mortgages, Rail Road Stock and Bonds, etc., must pay from three to five per cent. tax, on the income.

Banks and Bankers throughout the Country will continue to dispose of the Bonds; and all orders by mail, or otherwise will be promptly attended to.

The Treasury Department having perfected arrangements for the prompt delivery of Bonds; Subscribers will be enabled to receive them at the time of Subscription, or within Four days thereafter. This arrangement will be gratifying to parties who want the Bonds promptly on payment of the money.

N. B.—The above Bonds are furnished by

FISK & HATCH,
No. 38 Wall-st., New-York City.

BANKERS AND DEALERS IN

All kinds of Government and other Securities. Orders from the Country for purchase of Government Bonds, etc., attended to **WITH CARE** and Promptness.

As Agents for the sale of **U. S. FIVE-TWENTY YEAR SIX PER CENT. BONDS,**

Messrs. FISK & HATCH, are enabled to save parties all trouble and expense in finding Legal Tender Notes, or otherwise, investing in these Bonds. Orders or inquiries by mail will receive prompt attention, and the Bonds will be sent to any address, by mail or express, as desired. Payment may be made in BANK NOTES CURRENT IN NEW-YORK, DRAFTS AND CHECKS ON CITY BANKS, OR U. S. LEGAL TENDER NOTES. Persons in the country can send their orders and money to us direct, or call at the nearest Bank and ask the Cashier to do it for them. Drafts or Checks may be sent safely by mail. Bank Notes or Legal Tenders should be sent by Express,

A LADY WISHES EMPLOYMENT IN A kind family of some refinement. She understands most of the details of housekeeping, sewing, care of milk, &c., and teaches Music, with all branches of a thorough education. Address "INTEGRITY," 41 Park Row, New-York.

New-Jersey Farms.

To those wanting land for farming, trucking, or fruit growing, I am prepared to offer superior inducements, as I have a large quantity of good land, which I will sell at reasonable rates in quantities of from 5 to 200 acres.

The lands embrace all varieties of soil, with or without improvements, in good neighborhood.—Schools, Churches, Post-Office, Mills, and Rail Road depot in immediate vicinity. Situate on the Camden and Amboy R. R., 45 miles from New-York. For particulars apply to

JAMES BUCKELEW, Jamesburg, N. J.

ONE THOUSAND ACRES of the Best Farming Lands in Ocean County, N. J., for sale, near the line of the Raritan and Delaware Bay Rail Road. The soil is a dark sandy loam, lying on a clay subsoil, situated central between the Rail Road and Barnegat Bay.—Convenient to the Bay for fish, oysters, marine manures, and water communication to New-York. Easy access to the Philadelphia and New-York markets by the Railroad. Apply to

EDWARD BRINLEY, Perth Amboy, N. J.

TO RENT.—Farm of about 100 acres on Oldfield Point, near Setauket, Long Island—all necessary conveniences. Apply to
C. E. GROESBECK,
51 & 55 Broad street, New-York.

Mode of applying JOHNS & CROSLY'S
GUTTA PERCHA CEMENT ROOFING.

This Roofing is Fire and Water Proof, and can be applied by any ordinary laborer. It costs only about one-third as much as tin, and is more durable.

GUTTA PERCHA CEMENT PAINT applied to leaky roofs of all kinds, will render them perfectly water-tight. It is put up *ready prepared for use* and for shipment to all parts of the country. This Paint is particularly adapted for painting Out-houses, Barns, Fences, &c., &c., and will effectually prevent wood from decaying.

These materials have been tested on more than twelve thousand roofs during the past six years, and we can give abundant proof of all we claim for them. Full descriptive circulars and any required information furnished by the
JOHNS & CROSLY MANUFACTURING CO.,
78 William-st., cor. Liberty, New-York.

The NONPAREIL WASHING MACHINE

Is the only entirely reliable machine in use. It has been before the public two years, and has not in any instance failed to give satisfaction.

It saves two-thirds the labor and time required in hand washing.

It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it.

It will not get out of order.

It is recommended by Mr. Judd, the proprietor of this Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$30.

SELF-ADJUSTING and ADJUSTABLE!

The only Wringer with the Patent

Cog Wheel Regulator,

which POSITIVELY prevents the rolls from
BREAKING, OR TWISTING ON THE SHAFT.

It was pronounced superior to all others at the World's
Fair at London, 1862. It took the FIRST PREMIUM at the
great Fair of the AMERICAN INSTITUTE, New-York City,
1863, where the judges were practical mechanics, and ap-
preciated **COG WHEELS**.

It took the FIRST PREMIUM at the
New-York State Fair.....1862 and 1863.
Vermont State Fair.....1863.
Pennsylvania State Fair.....1863.
Iowa State Fair.....1863.
Illinois State Fair.....1863.
And County Fairs without number.

ORANGE JUDD, of the American Agriculturist, says of the
UNIVERSAL CLOTHES WRINGER,

"We think the machine much more than **PAYS FOR IT-SELF EVERY YEAR** in the saving of garments! There are
several kinds, nearly alike in general construction, but we
consider it important that the Wringer be fitted with **Cogs**,
otherwise a mass of garments may clog the rollers, and the
rollers upon the crank-shaft slip and tear the clothes, or the
rubber break loose from the shaft. Our own is one of the
first made, and it is as **GOOD AS NEW** after nearly **FOUR**
YEARS' CONSTANT USE.

We have seven sizes, from \$5.50 to \$30. The ordinary family
sizes are No. 1, \$10, and No. 2, \$7. These have

COG-WHEELS,

and are **WARRANTED** in every particular.

On receipt of the price, from places where no one is sell-
ing, we will send the **U. C. W.**, **FREE OF EXPENSE**. What we
especially want is a good

CANVASSER

in every town. We offer liberal inducements, and guarantee
the exclusive sale.

HILTON'S INSOLUBLE CEMENT!

Is of more general practical utility than any
invention now before the public. It has been
thoroughly tested during the last two years
by practical men, and pronounced by all to
Be Superior to any
Adhesive Preparation known.

Hilton's Insoluble Cement

Is a new thing, and the result of years of
study; its combination is on
SCIENTIFIC PRINCIPLES,
And under no circumstances or change of
temperature, will it become corrupt or emit
any offensive smell.

Boot and Shoe Manufacturers, using
Machines, will find it the best article known
for Cementing the Channels, as it works
without delay, is not affected by any change
of temperature.

Jewelers will find it sufficiently adhesive
for their use, as has been proved.

It is especially adapted to Leather,
and we claim as an especial merit, that it
sticks patches and Linings to Boots and
Shoes sufficiently strong without stitching.

IT IS THE ONLY LIQUID CEMENT

Extant, that is a sure thing for mending
Furniture, Crockery, Toys, Bone,
Ivory, and articles of Household use.

REMEMBER

Hilton's Insoluble Cement
is in liquid form and as easily applied as
paste.

Hilton's Insoluble Cement

Is insoluble in water or oil.

Hilton's Insoluble Cement

Adheres oily substances.

Steel Composition Bells.

THE AMERICAN BELL COMPANY.

(Office No. 30 Liberty-street, New-York.)

Are the only manufacturers of this descrip-
tion of Bell, either in this country
or in Europe—the combining of
certain metals, and the process
of manufacturing the same being
the discovery of the President
of the Company. These Bells
we can commend with great con-
fidence to the public, for their
cheapness and quality of tone.
We furnish a 500 lb. Bell with all
the necessary appointments—in-
cluding Harrison's patent-
ed Self-acting Rotary, for
\$100, and one of 1000 lbs.
with like appointments, for
\$200. The price for the
Bells being 15c. per pound,
and that of the hangings
of the first, \$25, and those of the latter \$42. Our circulars,
containing full details, will be forwarded free of charge to
all parties desiring the same.

Amalgam Bells,

At prices within the reach of every Church, School,
Cemetery, Factory, or Farm in the land. Their
use throughout the United States and Canada for
the past six years has proven them to combine
most valuable qualities, among which are **TONE**,
STRENGTH, **SONOROUSNESS**, and **DURABILITY** OF
VIBRATION, unequaled by any other manufacture.
Sizes from 50 to 5000 lbs., costing two THIRDS LESS
than other metal, or 15 cents per pound, at which
price, we warrant them twelve months. Old bell
metal taken in exchange, or bought for cash. Send
for a Circular to the Manufacturer.

PRINCE & CO., Flushing, N. Y.

FRUIT AND ORNAMENTAL TREES. RARE CHANCES OFFERED.

200,000 Choice Fruit Trees, Vines, etc., for sale, of varied size to suit customers.

The subscriber calls attention to his unusually large stock of well grown trees now on hand, and especially to the present stock of the STANDARD FRUIT APPLE, which is the largest and finest ever offered at these Nurseries.

With twenty years of experience, by careful observation and judicious selections, he believes he is able to judge and furnish what will suit his customers, as well as the varied soils and localities in which trees may be wanted. There is also special attention paid to local varieties, adapted to Southern and Central Pennsylvania, many of which have proven themselves more valuable, than sorts originating in a climate differing so widely from these sections.

He is also preparing a list of CLUB PRICES for those who purchase direct from the proprietor, offering rare inducements for neighbors to join together and get trees considerably under the regular retail prices.

This mode is adopted for those who may not have an opportunity to purchase from his regularly authorized agents, and hold a mistrust towards the too numerous tree vendors spread over the land.

The frequent use made of his name and establishment by strangers, to effect sales where the reputation of the nursery is known, compels him to warn all not to purchase—as coming from these Nurseries—stock offered by pretenders, who do not hold an authority from the proprietor.

Local or stationed agents will be accepted, but neither traveling nor stationary agency inquiries will receive notice, unless the parties produce satisfactory reference as to their honesty in dealing with customers and employer. Send for Catalogues and price list, which contain inducements not before offered by him. ABUNDANT AND TRUSTWORTHY REFERENCE WILL BE FURNISHED TO ALL WHO ARE STRANGERS TO THE ESTABLISHMENT.

Address DAVID MILLER, JR.,
Cumberland Nurseries, Carlisle, Pa.

Fruit and Ornamental Trees.

We offer a large stock at low rates of APPLE, PEAR, CHERRY, PLUM, and PEACH TREES of superior growth and quality.

MUNN & CO'S

ESTABLISHED 1842

During the past Twenty Years, Messrs. MUNN & CO., in connection with the publication of the WEEKLY ILLUSTRATED SCIENTIFIC AMERICAN (the only paper devoted to the Mechanic Arts in the Country), have acted as Attorneys for procuring Letters Patent in the United States and all foreign countries.

They would state that they have acted, during this period, as agents for more than

Twenty Thousand Inventors!

In fact, they have become identified with the whole brotherhood of inventors and patentees, at home and abroad. Thousands of inventors for whom they have taken patents, have addressed to them most flattering testimonials; and the wealth that has inured to the inventors whose patents were secured through their Office, and afterwards illustrated in the SCIENTIFIC AMERICAN would amount to many millions of dollars!

Messrs. MUNN & CO. never had a more efficient corps of Draftsmen and Specification Writers than those employed at present; and they are prepared to attend to patent business of all kinds, in the quickest time and on the most liberal terms.

For further information, send for a pamphlet which contains the Patent Laws of the United States, and much other valuable information of importance, to inventors and all others who own patent property. Also pamphlets of information furnished regarding the Patent Laws of all Foreign Countries.

For further particulars address MUNN & CO., 37 Park-row, New York, or corner F and 7th streets (opposite Patent Office), Washington, D. C.

THE AMERICAN STOCK JOURNAL FOR 1864.

NOW IS THE TIME TO GET NEW SUBSCRIBERS.

Fourteen Numbers for one Dollar!

One Premium of Taylor's South Down Buck Lamb worth \$50!!!

ONION CULTURE—Fourth (new) Edition.

This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by seventeen experienced Onion Growers, residing in different parts of the country. Price 20 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

SOMETHING TO DO.—"PLEASANT AND PROFITABLE." Good Books, ready sales, and good profits. Agents wanted. Address with stamp to FOWLER & WELLS, 308 Broadway, New-York.

A Book for all Churches.

THE CHURCH SINGER,

A COLLECTION OF SACRED MUSIC,

Published by
CARLTON & PORTER,

200 Mulberry-street, New-York,

is now ready.

A great proportion of the material for this work is the result of several years' labor of PROFESSOR C. C. CONVERSE, former Organist of the Broadway Tabernacle, New-York. It embraces the finest music collected and composed during a residence in GERMANY and ENGLAND, as well as the most popular tunes of AMERICAN AUTHORS, adapted to the hymns in use by all denominations.

The great number and variety of CHANTS and SET PIECES found in this work will greatly enhance its value, and the Publishers commend it to the notice of ALL CHURCHES as the BEST BOOK of the age, according to the testimony of persons competent to judge.

For sale by the Trade generally.

IK MARVEL'S NEW WORK.

Just published by C. SCRIBNER, 124 Grand-st. New-York.
MY FARM OF EDGEWOOD.—A Country
BOOK. By the Author of "Reveries of a Bachelor,"
&c., cloth, Price \$1.50.

The work has grown out of the author's farm experiences, but yet is not a literal transcript of those experiences. It embodies very much what the author would have said in way of advice, encouragement, and warning to any good friend who thought of making trial of country life. There are tempting dishes of fruits and sweet home-ly nosegays scattered up and down its pages; but there are also stories of annoyance—of chaffering bargainers, of pestilent depredators, of stupid teamsters, and of insoluble salts.

The author says in his closing chapter.—

"I think that I have not withheld from view the awkwardness and embarrassments which beset a country life in New-England, nor overstated its possible attractions. I have sought at any rate to give a truthful picture, and to suffuse it all—so far as I might—with a country atmosphere; so that a man might read, as if the trees were shaking their leaves over his head, the corn rustling through all its ranks within hearing, and the flowers blooming at his elbows.

Also Just Ready, by the same Author,

in neat pocket editions, \$1.25 each:

I. REVERIES OF A BACHELOR.

II. DREAM LIFE.

These books have now for twelve years retained popular favor. Three or four different editions have appeared in England, and as many more in France and in Germany. The aggregate issue of the first, in the English form, has not been less than 100,000 copies; and in French and German from thirty to forty thousand. The publisher therefore feels warranted in giving a new dress to these old favorites.

Copies sent by mail, post paid, on receipt of price.

TOBACCO.

Just How to Grow it.

Every particular, from the selection of the Seed, and preparation of the ground, to the Gathering, Curing, and Marketing the Crop, is given in a work issued by the Publisher of the *American Agriculturist*, and sent post-paid for 25 cents. This work consists of a selection of the best fourteen out of eighty-five Essays, prepared by eighty-five different cultivators, residing in various parts of the Northern and Middle States. In each of the Essays contained in this work, the writer tells, in a plain, practical, straight-forward manner, just what to do, and how to do it. Any item omitted by one is given by another, so that the information is full and complete. Several engravings illustrating the method of drying, packing, etc. The work is worth its weight in silver to every one growing even a small plot of tobacco.

THE PRINTERS' DEVIL.

A handsome 8 page literary and miscellaneous Family Paper, illustrated by Bellevue, Darley, and other first class artists, will be sent to any address SIX MONTHS ON TRIAL, for the nominal sum of twenty five cents. This affords a rare chance to secure a valuable journal for the fireside, at a low rate, and no lover of good reading should fail to send for it. The puzzles will be just the thing for the winter evenings, and the valuable prizes offered for solutions will add immensely to the fun. Address—

"THE PRINTERS' DEVIL," 113 Fulton-st. New-York.

[Extract from Editorial Notice in "Home Journal," Sept. 12] "Notwithstanding its name, which some might consider objectionable, it may justly rank with many of the periodicals of the day. Its contents are varied, and include tales, sketches, poetry, etc., for the elder members of the family, and a "Puzzle Department," "Prize Rebus," and other specialties for the juveniles. Possessing attractions of real merit, and maintaining a high moral tone, it is particularly adapted to the family circle, and cannot fail to have a good influence with the young."

BOOKS FOR FARMERS AND OTHERS.

[Any of the following books can be obtained at the office of the *Agriculturist* at the prices named, or they will be forwarded by mail, post paid, on receipt of the price. Other books not named in the list will be procured and sent to subscribers when desired, if the price be forwarded. All of these books may be procured by any one making up a library. Those we esteem specially valuable, are marked with a *.]

A GREAT WORK!

EVERY MAN HIS OWN PHYSICIAN.

THE NEW ILLUSTRATED HYDROPATHIC ENCYCLOPEDIA: A Complete System of Hydropathy, embracing the Anatomy and Physiology of the Human Body, Illustrated; Hygienic Agencies, and the preservation of Health; Dietetic and Cookery; Theory and Practice of Treatment; Special Pathology and Hydro-Therapeutics, including the Nature, Causes, Symptoms, and Treatment of all known Diseases. With 500 Engravings, nearly one Thousand Pages, including a Glossary and Index, complete. By R. T. TRAIL, M.D. Sent prepaid by FIRST MAIL for \$3.50. Address FOWLER & WELLS, No. 308 Broadway, New-York.

WANTED.

Agents are now wanted to travel in each County of the United States and Canada and procure orders for Rev. J. S. C. Abbott's GREAT HISTORY OF THE REBELLION, Splendidly illustrated with Steel Engravings, Maps, Charts, &c., &c. In two volumes. First volume now ready. Second volume to be issued after the War. For an appointment as agent or for information, apply by mail to HENRY BILL, Publisher, Norwich, Conn.

NEW MUSIC BOOK BY MR. BRADBURY.

IN PRESS,

And will be issued early in November,

THE KEY-NOTE;

A new collection of Sacred and Secular Music, for Singing Schools, Choirs, Congregations, and social use.

BY WM. B. BRADBURY,

AUTHOR OF THE "JUBILEE," AND MANY OTHER MUSICAL WORKS.

ONE HUNDRED pages will be devoted to the Elements of Music, with a great amount of new Singing School Music, and nearly THREE HUNDRED pages to Sacred Music, as Tunes of all metres, Anthems, Chants, and other Set Pieces, mostly new. The work is printed throughout from large plain type, one part on a staff. Price, \$10 per dozen. A single copy will be sent post-paid to any teacher of music or leader of a choir, for examination, on receipt of one dollar.

The immense success of Mr. Bradbury's previous works, and their almost unexampled sale (of his last work in this department, THE JUBILEE, more than two hundred thousand copies have already been sold), prove his knowledge of the wants of the public, and his ability to supply them.

The present work was designed for publication last year, but having been delayed because of the unfavorable times, the author has had opportunity to perfect it in its various departments. THE JUBILEE, more than two hundred thousand copies have already been sold, and complete, than its predecessors, while to Choirs, Congregations, Societies, &c., it will present the results of Mr. Bradbury's labors in composing and collecting for several years. For sale by MASON & HAMLIN, Boston. Published by MASON BROTHERS, 5 & 7 Mercer-st., New-York.

Ready Early in November.

General Butler at New-Orleans,

A History of the Department of the Gulf in the year 1862, with an account of the capture of New-Orleans, and a sketch of the previous career of the General, civil and military.

BY JAMES PARTON,

AUTHOR OF "LIFE OF ANDREW JACKSON," "LIFE OF AARON BURR," ETC., ETC.

MR. PARTON has had the best possible facilities for the preparation of this work, including free access to official documents. The capture of New-Orleans, and General Butler's administration there, form the most brilliant epoch in the present war, and those who are acquainted with Mr. Parton's previous works will anticipate a volume of intensest interest. It will be ready early in November, forming one octavo volume of about 700 pages. Price, in cloth binding, \$2.00. MASON BROTHERS, 5 & 7 Mercer-st., New-York.

AGENTS WANTED—TO TAKE ORDERS FOR

AVICTOR'S HISTORY OF THE REBELLION, the acknowledged Standard endorsed by the President, Cabinet, members of Congress, Governors, Senators, the Historian, and by the press generally. Two volumes are now ready, superbly illustrated with Steel Engravings. Sold by subscription only and exclusive territory given. Canvassers make \$50 to \$100 per week. Send for circular of terms &c. Address EDWARD F. HOVEY, No. 13 Spruce-st., New-York.

School Teachers Wanted.

To travel and solicit orders for Rev. J. S. C. Abbott's GREAT HISTORY OF THE REBELLION, in each County of the United States and Canada. The work is illustrated with Splendid Steel Engravings, Maps, Charts, &c. In two volumes. First volume now ready. For an Appointment as Agent apply at once to the Publisher HENRY BILL, Norwich, Conn.

MORAL PHILOSOPHY; Or, THE DUTIES OF

MAN CONSIDERED IN HIS INDIVIDUAL, DOMESTIC AND SOCIAL CAPACITIES. By GEORGE COOMBE. Reprinted from the Edinburgh edition, with the author's latest corrections. Large 12mo.; price \$1.25. New-York: FOWLER & WELLS, 308 Broadway. A contemporary says:

"This book is a treasure. It is the only American edition of the Moral Philosophy containing the author's latest revisions. It should be in the library of every lover of humanity. Health, happiness, progression, come from works of this stamp, and we heartily commend it to the world."

TO FARMERS AND OTHERS.

We are manufacturing a Genuine Article of VERY FINE, BONE DUST, and RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash,

Address A. LISTER & BRO.,

Newark, N. J.

BRUCE'S

CONCENTRATED MANURE.

Farmers wishing this valuable manure, will please send in their orders early for the fall crops. Sold at the old price, \$40.00 per ton. For Wheat, Rye, and Grass lands it has no equal. Send for a Circular, containing testimonials and directions for use. C. W. VAN DOREN & CO., 58 Cortlandt-st., New-York.

AMMONIATED PACIFIC GUANO.

A real guano containing from seventy to eighty per cent of Phosphate of Lime, to which has been added, by a chemical process, a large percentage of Actual Ammonia so fixed that it can not evaporate, making it equal if not superior to any other fertilizer.

Pamphlets with copies of Analysis by Dr. Jackson, Mass. State Assayer, and testimonials from scientific Agriculturists showing its value can be obtained from J. O. BAKER & CO., Selling agents, 87 Wall-st., New-York.

Postage on the Agriculturist is only 3 cents per quarter, if paid in advance by the recipient. The old dispute about the weight, is settled by the new law which allows 4 ounces instead of 3; no copy weighs 4 ounces in any case. Any postmaster who insists upon charging more than 1 cent per number, when paid quarterly or yearly in advance, is either too ignorant to hold office, or is guilty of extortion. We ask the name of any one who hereafter exacts more than the above amount of postage, as has been illegally done hitherto, in some cases.

Friend "B's" Objections.

"B." writes: "I confess I get many times my dollar's worth from the *Agriculturist*, and like it almost first-rate now; but I would like it better if the publisher would not say so much about premiums, business matters, getting subscribers, etc., on the last page."

That is frank and friendly, and we like it. But, friend "B.," if you now get your money's worth 'many times,' why object to our using a page or two for business items? Please consider that it is only by pushing along the circulation, that we are able to devote so much expense to the preparation of the reading matter, to collecting information, to procuring engravings, etc. The larger the circulation, the more can we return to every reader for his money. We can supply a much better paper for a dollar a year, than we did eight or ten years ago, though we then gave the best one we could for the money.

Again, is not every farmer who reads any good paper devoted to his occupation, likely to think more about his work, to lay out better plans, to learn what pays best, and to labor more systematically and profitably, than he who plods along in the old way, getting no hints or suggestions from others engaged in like pursuits? Would it not be better if every man, woman, and child, read some such paper, than if all were living secluded from the outside world, like the Japanese, without much access to what others are doing and thinking—just as about four millions of farmers are now doing in this country? We think so, and aside from any personal interest in the matter, we believe we are doing a good work by pushing this journal into every family possible. With this view of the case we must keep on—urging people to read, offering special inducements to them in a variety of ways, asking our readers to solicit the attention of others, offering premiums to those who do so, and thus keep up an interest. When every body is brought to read, to talk, to think about improved modes of tillage, better and more profitable stock and implements, fruit growing, gardening, beautiful flowers, the best methods of cooking, and doing other household work, etc., etc., what a change will be produced! How much better off, and how much happier will the great agricultural class be. Give us your help, friend. Stir up all your neighbors, and induce them to get a paper that will pay them "many times its cost," as you say it does you. If they don't know what a feast there is for them, go out and "compel them to come in." And we, too, must keep doing. If our own books could hold no more names, we would even work for some other good journal—any way to get all the people to reading and thinking. An ox has very good muscles for mere working purposes: it is the MIND that makes the MAN.

Condition of the Strawberry Plants.

As the Great Strawberry Plant was purchased, and is being cultivated and multiplied expressly for the subscribers to this journal, they will doubtless be glad to hear of its welfare occasionally. We are happy to report, that from the few plants first obtained (that is, all there were in existence) we have so far succeeded in getting plants enough to set out an acre. No expense or labor is being spared to multiply them as rapidly as possible. They are looking well, and we have no reason to regret the enterprise. The extraordinary dry season is very greatly diminishing the rapidity of the multiplication. Several thousand buckets of water have been applied, but the soil, ordinarily so wet as to be underdrained, is almost "as dry as an ash heap." The only effect, however, will be to delay the distribution a month or two longer than would otherwise be the case. We have not the slightest doubt of being able to distribute next season at least 40,000 to 50,000 plants—good strong ones, too, and not little puny things, such as have been sent out from some drouth-parched localities this year.

To answer numerous letters of inquiry, we say, that no one who has applied thus far, or who shall apply for some weeks to come, will fail to be supplied next season. We hope and expect to favor every subscriber for next year with at least one good plant, though to prevent any disappointment or misunderstanding, we promise only to send them as far as they go, sending to subscribers in the order of application—"first come, first served." As soon as any subscription is received for 1864, the name is also entered for the strawberry plant, if desired. The plants can go by mail safely, and this will be the best way generally, but those who expect them thus, should remember to forward the 5 cents in addition to the subscription, to meet the expense of postage and oil cloth. To prevent confusion or irregularity, let the application for the plants always come with the subscription for volume 23. We repeat, that the plants, as far as they go, will be presented to all subscribers for 1864, who apply for them—old and new subscribers, whether coming singly or in clubs, on premium lists, from agricultural societies, or otherwise.

Thirteen for Twelve.

All New Subscribers for 1864, received this month (November), will be supplied with the December number without extra charge. Those arriving during the first week, will also receive the Nov. number, or 14 months.

N. B.—The above offers extend to all new subscribers, whether they are received singly, or in clubs, or on premium lists, or from Agricultural Societies, or otherwise.

N. B.—Since many old subscribers are renewing in advance, it is important that new subscribers' names be marked as "NEW" when sent in, if the extra numbers are desired, for we shall not send these extra numbers unless they are specially and definitely asked for.

Good Pay.

Again we call special attention to the list of good articles on page 346, offered as pay to those who gather up clubs of subscribers. The various articles offered are valuable, are generally wanted, and not difficult to obtain, if any one sets about it in good earnest. Many thousands of persons have secured one or more of these, with no outlay of money. The premiums are forwarded as soon as the names are received. The extra number offered above, makes it easy to secure lists of new names this month. Please read the terms and the descriptive notes.

Yes—Six Years for \$5.

Several subscribers, especially on the Pacific Coast, have from time to time asked if they could not just as well send on \$5 for five years, and thus save the trouble of remitting a small sum every year. This would be convenient where dollar bills are not common. We answer, yes, and even better than asked, those who prefer to do so, can, for \$5, receive a receipt for six years.

Specimens or Extra Numbers are costly, and each copy requires two cents postage paid in advance. So they cannot be scattered around very freely. When needed for canvassing, the judgment of the applicant will in each case decide whether both the paper and postage should be supplied by the Publisher. Unless used solely for our benefit, postage at least should be provided.

CLUBS can at any time be increased, by remitting for each addition the price paid by the original members, if the subscriptions all date at the same starting point. The back numbers will of course be sent to added names.

Back Volumes & Numbers Supplied.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound, \$1.00 each.

PRICES WHEN SENT PREPAID BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, 20, or 21, unbound, \$1.24 each.

Volumes 16, 17, 18, 19, 20, or 21, bound, \$2.00 each.

Single numbers of any of the above Volumes, 10 cents each.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year, \$1.00
Six copies, one year, 5.00
Ten or more copies one year, 80 cents each.

Add to the above rates: Postage to Canada, 12 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only three cents a quarter, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 384.

VOLUME XXII—No. 12.

NEW-YORK, DECEMBER, 1863.

NEW SERIES—No. 203.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Suggestions and Notes for the Month.

The clock strikes Twelve! The hands have moved steadily around earth's broad dial-plate, marking off the months and the seasons, the snows and frosts of Winter, the flowers and new vegetable life of Spring, the glowing beauties of Summer, the fruits of Autumn, and the chill blasts that warn man and beast to again seek shelter and protection while the frost king reigns. The year is an epitome of life—its budding infancy, its joyous youth, its vigorous manhood, and age shorn of its strength. There is this difference, however: a life of failures can never be remedied; the errors and deficiencies of one year may be corrected in the next, if it be allotted to us. It is well, therefore, to carefully scan the immediate past, and gather lessons of wisdom for future guidance. Let, then, this closing month of the year be devoted to a careful examination, not alone of our business plans, our successes, and our failures, but of our motives and aims, as well. He is not living wisely nor well, who does not earnestly aim to make each coming year better than the past one, better for himself and for others. No one lives alone; no one is so humble that his daily life, his acts, his words, and even his countenance, do not exert some influence upon the thoughts, feelings, aims, and actions of another. Mere regrets for the past, or simply wishing and intending for the future, are not sufficient. It is truly said that "good wishes and good intentions pave the entire pathway of the lost."

Earnestness and promptness are talismanic words. In all plans for moral improvement, "to-morrow, or on such a day," is too often the fatal error in our calculations. To-morrow always has its to-morrow. To-day is the word. To make next year's efforts most successful, begin the work of improvement to-day....

This paper closes our editorial labors for 1863. While we have earnestly striven to make this volume not merely acceptable but profitable to our grand circle of readers, we can see where still more might have been done. Strong in the purpose to remedy past defects, and to do more than ever before to promote the prosperity and happiness of our readers, we now begin the labors of volume 23. Expecting to enjoy the company of all our present readers, we will not stop to say any farewells, but on to our work.

The artist's vignette for this month tells of children on their way to the school room. There is food for thought here. We who have passed the meridian of life, have lost much time that can never be regained. Errors of the head and heart may, and must be rectified, though it requires strong effort to turn out of the ruts and channels already deeply worn. But the generation to follow us is yet in the plastic period. The boys and girls of to-day can be molded in thought, feeling, and purpose, much as we will. If we guide and train the young wisely, the error and wrongs of the present generation will be remedied in the next.—With farmers, especially, this is the school season of the year. Even those children whose labors have been indispensable during the busy Summer, can now be spared to devote some time to mental improvement. An especial glory of American Institutions is the Common School, open to the common people without distinction. Let them not be common in quality. Nine-tenths of the great men and women of our country received only a common school education.

Let every parent remember that beneath the exterior of the dulllest child is concealed a gem that needs but to be polished, to make it shine with brilliant lustre. Let every American citizen do his best to foster and cherish the public school. Go to the school meetings, leaving behind every vestige of a political, sectarian, or personal feeling. Talk, vote, and act, as public spirited citizens. Spare no labor or expense to make your school building attractive within and without. A few dollars extra tax to secure good, well warmed, and well ventilated rooms with pleasant surroundings, and especially a competent instructor, are far better expended than if devoted to securing a little finer clothing, or to paying doctors' bills, and the costs of protecting society against the depredations of the badly trained. Visit the school room very often to show your interest in what is going on there; it will encourage and stimulate both teacher and scholar to higher purposes and greater

efforts. Who does not remember the good effect of a visit to the school from even the poorest man or woman in the neighborhood. Let the visits be systematic as well as frequent. It often makes us sad to see a man *constantly* attentive to the wants, the comforts, and the progress of his dumb animals, while he never goes near the place where his children are daily trained for weal or woe.

Work for the Farm, Household, etc.

Accounts.—The present is of all times in the year the best to establish a thorough method of farm accounts. Mature a simple, easy and accurate plan, and between this and the first of January, old accounts may be at least got out of the way, so that their settlement need not interfere with taking a new start with the New Year. Well kept farm memorandums and accounts will be a source of no small actual profit, besides settling facts, proving dates, preventing prosecutions and lawsuits, and oiling the machinery of social life. Book-keeping is a simple art, though generally made a mystery.

Animals.—Shelter and food, cleanliness and ventilation.—The better the shelter for horses, neat stock and swine, the less food will they consume; if ventilation be provided, and they be kept clean, they will be healthier and more profitable. Pigs as well as horses show the good of clean bedding and dry pens in Winter.

Buildings.—Tidiness about farm buildings marks the thrifty farmer, and it is a virtue which grows by practice. The comfort of the family and the herd are alike promoted, and in this as in many other things, there is as strong an appeal to the pocket and to the conscience as to the principles of good taste. He who neglects little matters and can only "slick-up" now and then when he makes a regular business of it, is an untidy and probably a thriftless farmer. If you propose building, be satisfied with no plan until it is most thoroughly studied. Alterations and frequent repairs are costly luxuries.

Cows in our climate and in the system of farming usually followed, are during the Winter in a delicate condition: early preparation should be made so that an injured or sick cow may be removed from the rest to the hospital (a box-stall in an adjacent apartment). This is best even for slight injuries, for a cow may unexpectedly slink her calf and others "follow suit." Throw earth on slippery paths about the water-trough in freezing weather. Milk young cows to within 5 weeks of calving, to fix a long milking habit. Feed generously, for not only the size and character of the calf is affected, but the amount of the milk during the entire season following.

Corn-Fodder.—Well cured corn-fodder is worth just as much as good hay. It needs a greater expenditure of labor to prepare it so that cattle will eat it clean, but cut up and torn or crushed as is done by some feed-cutting machines, wet-

ted and allowed to stand a few hours with a sprinkling of salt, or oil-meal mixed in, it will be eaten with great relish. When hay is high and corn scarce, it is a pity to have any of it wasted.

Farmers' Clubs.—He who neglects opportunities to meet and talk over agricultural matters with his brother farmers loses much. See to it if possible that there is some regular neighborhood meeting of farmers, and their wives and adult children, to secure improvement in farming and kindred things.

Fence Timber.—As fence mending and setting is one of the first duties after the frost is out of the ground, so a standing job for the Winter is the getting out of a good supply of posts, rails, and stakes. Let it not be forgotten.

Feeding-Racks and Troughs should be substantial, sheltered, under roof if possible, always kept clean.

Grain.—Few farmers can afford to risk the holding of grain for higher prices. If possible, make sales by showing perfectly fair samples, and arrange to deliver it when there is good sleighing. Grain loses in weight by drying, and proportionately increases in value, but rats, mice, and weevils cause it to lose weight also, and this is a dead loss, besides risk of bad roads, broken harnesses, etc.

Grain-fields.—The wandering of cattle over the grain and grass fields, particularly when covered with snow, and in thawing weather, is to be avoided. Snow-drift dams should be cleared away, and standing water drawn off.

Horses.—All horses, young and old, should have warm, comfortable shelter, be cleaned daily, and, if used, blanketed, both in the stable and out of it—the stable blanket being the lighter, and not covering the neck. Colts and horses from which no labor is required, need no blankets in moderate weather, or in a warm stable. All horses should be well shod, and the calks kept sharp in Winter.

Ice.—The experience of last year will lead to the securing of the first crop of ice. This is well, for it is ordinarily the best. If snow falls upon clear "black" ice, it will ordinarily pay for family use to sweep off the snow from a sufficient surface to fill the ice-house, so that in case of a rain and subsequent freezing, the upper stratum of ice will not be soft snow-ice, and that the cold may penetrate more readily. See article on ice-houses, page 362.

Manures.—It is best to keep manure under cover and enclosed, so that a slow fermentation will be constantly going on. Too active fermentation is very injurious; it may be checked by packing it very close by the treading of animals, spreading level and keeping hogs upon it, or working it over. The latter secures an evenness of fermentation while it prevents burning or fire-fang.

Muck from the Swamp.—The present month ordinarily affords a very favorable opportunity to get out muck. Leaving it in heaps during the Winter, it becomes acted upon by the frost, and is much better for use in the Spring, or to be carted to the stables during the Summer for use next Winter. If needed for use at once in the stable, haul it as soon as it is dry enough, and keep it under cover, or it will be of little service as an absorbent.

Meadows.—It is very poor policy to let cattle browse the meadows in Winter, or even wander over them. When not covered with snow in thawing weather, they injure the roots; and the places of cattle paths through the snow are often traced by dead grass and bare spots in Spring.

Poultry.—To secure a supply of eggs keep hens in a light, warm, airy room, feed plentifully, giving regularly some animal food—oyster-shells pounded fine, or some other form of lime. A little pulverized white arsenic in the whitewash will destroy lice effectually. Fowls choose the highest part of the house to roost in, and if there be not good ventilation, they will sometimes suffocate.

Sheep.—Nature protects sheep well against the cold, but they suffer from soaking rains. They are healthier if they have open dry sheds to stand or lie under in wet weather, and a good dry yard.

Sheep are seldom diseased if they are thus treated, have access to salt, and have enough good feed.

Swine.—In the course of this month the pens will be for the most part cleared of fat hogs, and only breeders and store hogs left. Let these have dry, warm quarters, with rye or wheat straw for bedding; feed generously, so as to keep them in good growing order. Regular feeds of roots, with a little grain daily will show well next Spring.

Tools.—Winter is the time of all others to look over and put tools in order for Spring and Summer work. And at no time are good implements so much injured by exposure as now, when it is wet and freezing, or warm and dry alternately.

Wood.—Now the swamps are, or soon will be frozen, and we must secure a full supply of firewood, and wood for other purposes also, cut ready to be drawn to the house at the first good sleighing.

Orchard and Nursery.

If the Fall work has been performed in its season, there is little to be done now. Sales and planting are over, and the nurseryman can now arrange his plans, and prepare for the Spring's business, which promises to be very active. During a mild spell, ground may be plowed and prepared for planting, and at these times draining, often so necessary in an orchard, may be successfully prosecuted. Trees which were temporarily heeled in for the filling of orders, should be looked to, and if the work was not thoroughly done, the roots should be earthed over so as to prevent freezing.

Cions may be cut on any mild day, and preserved in slightly moist earth or sand, in a cool cellar. In cutting, select vigorous well ripened wood of the past season's growth. Tie up and label each sort carefully, and to guard against the loss of the label it is well to cut a number on one of the largest cions in the bundle which should correspond with a number on a memorandum list. In procuring grafts for setting, take only varieties you have proved yourself, or those having such a reputation that there can be no risk of getting a worthless sort. Many persons seem to think that it is only necessary to graft a tree to secure good fruit, and do not reflect that it is as necessary to be careful about the character of their cions as it would be if they were purchasing trees.

Fruit either in the fruit-room or cellar should be kept at as low and uniform a temperature as practicable without freezing.

Manure may be applied to trees, and compost carted to places where it is to be used in the spring planting. Surface manuring as described on page 370, has many advantages; the coating of manure prevents injury from sudden alternations of temperature, while the soluble parts are diffused through the soil, enriching it without injuring the roots of the tree by actual contact with the manure.

Mice and Rabbits do much injury to newly planted trees, especially when there is snow upon the ground. Various protections have been suggested from time to time in these columns. After snow has fallen, tramp it down firmly around the trunks of the trees so that the mice cannot work through it. Rabbits should be trapped. Shields of tin and drain tiles are sometimes used.

Nursery Rows not plowed, may be worked whenever the ground is open. Throw the earth against the rows, leaving the furrows as surface drains. See that stakes in the nursery are legible and firmly fixed in the ground. While no careful nurseryman will rely upon stakes alone for the identity of his trees, it is always a great convenience to have them. New stakes and labels can be prepared to meet next season's demands.

Root grafting can be done in the house on rainy days, the grafted stocks being carefully put away in boxes of sand, and each sort unmistakably labeled.

Winter pruning is not to be recommended where large limbs are to be removed. Small ones left at the summer pruning may be removed by the knife.

Kitchen Garden.

If the weather is severe or the ground is covered with snow, there is but little to be done here. But if the month should be mild, some of the neglected November work may be attended to now. Clearing up, which is generally postponed until Spring, should be done, and all rubbish put out of sight. The garden will not only look neater during Winter if this is done now, but valuable time will not be consumed next Spring in clearing up after last season's crops. Whenever the state of the soil will admit, it may be thrown up into ridges with the plow, or spaded as directed on page 370. But few special directions can be given, and these are all comprised in the general one to do everything possible to facilitate operations in Spring.

Asparagus.—If the beds have not been covered with manure, they should receive a thick coating.

Bean poles, stakes, and all brush needed in the garden can be cut and stored for next season.

Celery.—If any still remains out, store it as directed in the fuller Calendar for October.

Cold Frames.—Give plenty of air whenever there is no danger of freezing, removing the sash altogether on mild days. As severe cold weather comes on, bank up around the frames with stable manure, and cover the sash with mats or shutters.

Compost and Manures.—Much of next season's success will depend upon the care given to accumulating these during the Winter. Every fertilizing material should be saved. Have a good supply of muck on hand to throw into privies, hog pens, and the barnyard. If muck cannot be procured, use some other absorbent; forest leaves answer to increase the stock of manure, and black earth is better than no absorbent for the liquid portions. If manure is carted to the garden, cover the heap with earth to keep it from washing by the rains.

Hot Beds.—Repair frames, glaze, and paint sash, and make all in readiness. If new ones are needed, have them made. Collect manure and leaves.

Pawnings and Salsify.—When the ground is open, take to the cellar a good supply for use in freezing weather, and cover with sand to prevent wilting.

Rhubarb.—Cover the bed with stable manure.

Seeds: clean and carefully put away any not already cared for. Keep no rubbish in the seed bag, such as old seeds, or those of which the identity is not positive. Exchange choice sorts with neighbors.

Tools.—Rainy days can be profitably employed in repairing and painting. Many an implement goes among the old iron, which a small expense for blacksmithing would make as good as new. The character of a gardener can be pretty accurately judged by a look into his tool house.

Fruit Garden.

New grounds may be prepared if the weather is suitable. Give the borders a good mulch of manure. Prune currants and gooseberries, and save the cuttings in the cellar for Spring setting. Prune grape vines and lay down the vines, giving the tender sorts a covering of earth. Bend raspberries down and cover with earth. Strawberry beds should have their winter mulching, taking care not to cover too deep; only an inch or two over the crowns. It is the earth rather than the plants, that needs covering.

Flower Garden and Lawn.

The directions of last month apply in general to this. But few things can be done, except to protect those shrubs and plants which are still uncared for—according to the hints given in November. If the month is favorable, new walks and borders can be prepared. If new improvements are proposed, first accurately measure the land and make a plan upon an exact scale, on paper. When the plan is done, let it be submitted to the criticism of judicious friends, who may be able to see faults and suggest improvements which did not before manifest themselves. In laying out new grounds, or extending those we already have, there are two

things to be borne in mind: 1st, to have no larger grounds than can be well kept, and the style such as will be in harmony with the general expression of the whole estate. It is in poor taste to lay out elaborately ornamented grounds, with vases and statuary, when the house plainly says that these are out of place. All embellishments should be made in view of the dwelling as the crowning point of the whole. Trees, shrubs, and pleasant walks, may lead to a house of the most moderate character, but it is only when the house has some pretensions to architectural display, that highly ornate grounds are appropriate. 2nd, in all plans for planting, have reference to the appearance of the grounds ten or twenty years hence. It is often the custom to plant thickly at the beginning, with the intention of thinning out the trees when their size requires it. Thinning is seldom done, as it demands more courage than most people possess to cut out a tree that has grown under their own eyes and care for many years, and as a consequence, a great many grounds are seen in which the trees have grown up to a perfect thicket. Though the place may look rather bare for a few years with young trees planted at proper distances, it will be more than compensated by a finer development than is possible, where they are crowded for present effect.

Evergreens.—If the suggestions given in the Spring have been followed, the grounds will now be cheerful with the pleasant verdure of various evergreens. A little care will be required to keep the branches from breaking under the weight of heavy snows. Remove the burden by jarring the trees. Junipers, Yews, and other pyramidal evergreens may be protected by winding a strong twine spirally around them so as to keep their branches upright. Protect Rhododendrons and other broad-leaved sorts by a screen, as directed last month.

Climbers.—When Wistarias and roses winter-kill, remove them from the trellises and protect by a slight covering of earth. Hardy, climbing roses will be benefited by simply laying on the ground.

Lawn.—Top-dressings of fine manure and of leached ashes may still be applied with benefit.

Roses.—Protect the less hardy sorts by bending down and covering with earth, or if this is not practicable, take up the bushes and cover their roots and tops in a dry place, deep enough to prevent freezing. A friend informs us that he has found hard coal ashes to answer very well for covering, as this material does not retain much water.

Green and Hot-Houses.

The general directions given last month are appropriate to the present one. The chief matters for attention are heat, moisture of atmosphere, and ventilation. December is often a month of sudden changes, and watchfulness will be required to guard against these. In the green-house, fire will not be needed (except on damp and foggy days), unless there is danger of the mercury going below 40°. The temperature of the hot house should be adapted to the nature of the collection.

Bulbs should be brought from the green-house into the warmer apartments.

Camellias.—Syringe the foliage and water freely.

Heaths need water as time of blooming approaches.

Insects.—Keep in check from the start; fumigation and whale oil soap will destroy the most of them.

Roses.—Start cuttings for a good summer supply.

Water.—Give to growing plants, and keep those at rest as dry as they will bear without wilting. Stimulate lagging plants with a little liquid manure.

Apiary in December.

Prepared by M. Quinby—By Request.

The temperature of a colony of bees must at all times be kept above the freezing point; they can generate heat only by the consumption of honey. The horse or ox, exposed to all the inclemencies of the weather, consume much more provender than when protected by the warm stable. So with bees exposed to cold, they require more than when housed. Small colonies often cannot gener-

ate sufficient warmth to prevent freezing. Large stocks will eat scarcely any more honey in maintaining the proper degree of heat, than medium sized ones. The advantage of housing bees in large numbers is, it takes less honey to keep up the proper warmth; small colonies are warmed by their proximity to large ones. This is realized only when fifty to one hundred hives are put into a room, to make it warm. To get rid of the moisture in such a room, the hives may be turned bottom up, without any risk. If the temperature cannot be kept above freezing nearly all the time, the utility of housing them is doubtful. When bees are kept out of doors, other things must be regarded as well as keeping them warm. Wooden hives, when made of double thickness, will need openings, to let out the moisture, and through these much heat escapes. Hives made of straw, and perhaps rushes and flags, may be entirely closed, except a small opening at the bottom; for the moisture will pass out, while the warmth is retained. Ordinary colonies in well made straw hives, will winter outside just as well as those in the house. A strong colony, with abundant stores, and a sufficient supply of air in the wood hive will stand in almost any situation, with numbers only slightly diminished, while the small ones often fail. Hives can be made warmer by surrounding with hay or straw, but this does not assist in disposing of the moisture. Air passages large enough to admit mice, should be covered with wire-cloth, so as to exclude them, but allow the bees to pass. Such colonies as are housed, should be put in the first really severe weather. If any need feeding, turn the hive bottom up, and lay pieces of honey directly on the combs; candy can be fed in this way.

The Pumpkin Show.

This exhibition was not quite equal to that of last year, because: First, the dry weather was very bad for squashes and pumpkins; and second, those who had fair crops, remembering the splendid exhibition of last year, held back their specimens fearing that they would be excelled by others. A number who have fine squashes of 100 to 150 lbs. weight, now tell us they would gladly have exhibited them, but the 200 to 300 pound squashes shown last year scared them out of any attempt to compete. Still, fine specimens and novelties were exhibited. One of the most striking things was a large gourd from Waldo F. Brown of Oxford, Ohio, called the "Sugar Trough Gourd." The specimen is shaped somewhat like a flattened pear, and is about 16 inches in diameter. When divided and cleaned, the thick woody shell forms two capacious bowls, which may serve as sap-troughs, and for various domestic uses. One of these which had been used for gathering sap for fifteen years, was sent with the whole specimen; it looks as if it might do service as much longer. The Yokohama (see page 372), and Turban squashes attracted attention. The Turban, so called from its peculiar shape, is fine grained, sweet, and of good flavor. According to Mr. Gregory, it requires to be planted early and have plenty of room, as it is a ranker grower than the Hubbard. The yield this season (a poor one for squashes) was six tons to the acre. They were grown on land in high culture, planted 8 x 8, and but one vine left to the hill. This variety was judged by a majority of the Committee to rank next to the Hubbard as a table squash, while one member gave preference to the Yokohama. We consider both varieties very fine, and the question of superiority difficult to decide upon single specimens.

The following is the award of the Committee, Messrs. Wm. S. Carpenter, Geo. Carpenter, and E. S. Williams:

1ST PRIZE; for Heaviest Specimen, 100½ lbs., to P. Kearne, gardener to William Shaw, Staten Island, \$10.
2ND PRIZE; 2nd Heaviest do., 95½ lbs., to same, \$5.

3RD PRIZE; for 3rd Heaviest do., (a Lima squash) 63 lbs., to George L. Jackson, Flushing, N. Y., \$3.
4TH PRIZE; for Best Squash for table use (Hubbard), to James J. H. Gregory, Marblehead, Mass., \$5.
5TH PRIZE; for Second do., (Turban) to same, \$3.
6TH PRIZE; for largest yield on a single vine (22 specimens, very fine, aggregate weight, 419½ lbs.,) to Rev. Charles C. Keyes, West Morrisania, N. Y., \$10.
7TH PRIZE; for second do., (3 specimens, aggregate weight, 168½ lbs.,) to Geo. L. Jackson, Flushing, L. I., \$5.
8TH PRIZE; for largest and best collection of Fancy and Ornamental Gourds (90 specimens), to William F. Heins, Morrisania, N. Y., \$7.
9TH PRIZE; divided equally between W. B. Westcott, N. Y. City, and J. C. Williams, Mont Clair, N. J., \$5.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed on our tables for exhibition, since our last report:

FRUITS.—Apples: Roman Stem, by Mrs. Van Rensselaer, Burlington, N. J.... Vandevere and Northern Spy; George A. Read, Deep River, Conn.... Sweet and Sour Apple; F. A. Reed, Fredericktown, Conn.... Golden Russet and Baldwin; S. M. Howard, Perry, N. Y.... Gloria Mundi, 23½ oz.; Jacob Erwin, Westchester Co., N. Y.—Pears: Penn; Rev. A. P. Buel, Borden-town, N. J.... Beurre Diel; T. Hagadorn, Williamsburgh, N. Y.... Beurre Diel grown in triplets; Col. Dillon, Brooklyn, N. Y.... Duchesse; B. F. Seaver, Orange, N. J.... Catillac, 23 oz.; J. L. Miller, Richmond, N. Y.... Duchesse and Beurre Diel; William Chorlton, Staten Island.... Beurre Clairgeau beautifully colored; Richard Hales, Aurora, N. Y.... Vicar of Winkfield; C. M. Morton, Hightstown, N. J., and Mr. Devoe, Paterson, N. J.—Grapes: Union Village, Catawba, Taylor's Bullit, Concord, Diana, Herbemont, Creveling, To Kalon, Delaware, Rebecca, Elsinburgh, Anna, Isabella, and Hartford Prolific; Rev. J. Knox, Pittsburgh, Pa.—Miscellaneous Fruits, etc.: Fine Hickory Nuts; Isaac F. Stover, Erwin, Pa.... Seedling Raspberry from Catawissa; Dr. Hollick, Staten Island.... Cranberries; W. I. Spence, Blue Point, N. Y., George A. Bates, Bellingham, Mass., Wm. H. Starr, New-London, Conn., T. E. Bridger, Suffolk Station, N. Y., James Gamog, Tolland, Conn., and E. Dubois, Lakeland, N. Y.... Chinese Quince; H. Coger, Factoryville, N. Y.... Winter Cherry, Isaac Haring, Piermont, N. Y.... Apple Quince, 16 oz.; J. L. Miller, Richmond, N. Y.... Large Chestnuts; E. S. Lamoreux, N. J.

FLOWERS.—Chrysanthemums; James Wissing, New York City.... Dahlias, fine collection, from Orphan Asylum, and from James Gordon Bennett, N. Y. City.... Rose, Miss Stumpf; Isaac Buehnan, New York City.... Pompon Chrysanthemums, splendid Bouquet; H. T. Haviland, Williamsburgh, N. Y.... Chrysanthemums, fine collection; Wm. F. Heins, Morrisania, N. Y.... Cut Flowers; W. B. Westcott, N. Y. City.... Beautiful Bouquet of out-door flowers; Miss M. A. Cortelyou, Staten Island, N. Y.... Chrysanthemums; Mrs. W. E. Meserve, Hoboken, N. J.... Dahlias; J. D. Hagaman, Harlem, N. Y.

VEGETABLES.—Chinese Egg Plant; J. D. Hagaman, Harlem, N. Y.... Sugar Beet and Mangel Wurzel; Geo. A. St. John, Norwalk, Conn.... Carrot, very long; Rev. N. Brown, Jersey City, N. J.... Red Onion; Francis A. See, Greensburgh, N. Y.... 2 California Tomatoes, 2½ lbs; John Metz, Hudson City, N. J.... Large Cabbage; G. A. St. John, Norwalk, Conn.... Purple Top Swede Turnip, P. C. Barnum, Hempstead, L. I.... Cow Horn Turnips; Wm. Blair, Hackensack, N. J.... Brussels Sprouts, Scotch Kale, Broccoli Sprouts, Cauliflower, Silver Skin and Red Onions, and Rosette Collard Cabbage; Wm. Erwood, Sen'r, Deer Park, L. I.... Sweet Potatoes; J. C. Thompson and J. W. Davis, Staten Island.... Turnip Beets; Mr. Carpenter, Pokeepsie, N. Y.... Potatoes, Pink-eyed Rusty coats, Coppermine, Garnet Chiff and Cuzco; E. Williams, Mont Clair, N. J.... Vegetable Egg Gourd; Mr. Bound, N. J.... Large Cauliflower from native seed; O. Judd.... Egg Gourds, Wm. C. Bryant, Brooklyn.... Purple Broccoli; F. Heeyer, Melrose, N. Y.... Carrots, curious, Dudley P. Ely, South Norwalk, Ct.

MISCELLANEOUS.—Osier Willows; E. Bridger, Suffolk Station, N. Y.... White Willow; James Reeder, Borden-town, N. J.... Rhubarb Wine, Louisa Capner, Flemington, N. J.... White Flint Corn; G. A. St. John, Norwalk, Conn.... Yellow Flint Corn; Misses Van Wyck, Fishkill, N. Y.... White Maryland Dent Corn; Mr. Hollinger, Weehawken, N. J.... Tricolored Sweet Corn; Col. S. R. Hazard, Newport, R. I.... Curious growth of grass through potatoes; L. A. Ladd, Greensburgh, N. Y.... Dent Corn; Josiah Valentine, Shrewsbury, N. J.... Yellow Flint Corn; B. P. Jones, Clinton Point, N. Y.... Balsam Pear (*Mormordica balsamina*), Michael Van Name, Jr., Mariner's Harbor, N. Y.... Spanish Leaf Tobacco; J. Reeder, Duck Island, N. Y.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

To Use the Index—Binding.—Instead of cutting down the reading matter as usual, we present the Title-page and Index on a separate Sheet, involving an extra cost of over \$500, which is a gift of so much to our readers. The Index sheet can be bound or stitched in front of the January number, to complete the volume. Numbers of any volume sent to the office will be bound in neat black covers with gilt backs, for 50 cents each, which hardly covers the present cost. Any missing numbers will be supplied at 10 cents each. Those desiring them can get the Covers for any volume (back to and including Vol. XVI.) They are ready prepared for the insertion of the numbers by any bookbinder. Price 25 cents each; they cannot go by mail.

Volumes and Numbers for Sale.—We have all of the Volumes from 16 to 22 inclusive, (1857 to 1863,) and can print more from stereotype plates as wanted. Price \$1 50 each, if bound—or \$1 each if not bound. If to go by mail, add 24 cents postage on an unbound Volume, or 45 cents if bound. Any single number of the above volumes sent post-paid for 10 cents.

A Hundred Good Items for this month's Basket are crowded over. The Basket for next volume will alone contain perhaps 2,000 or more of these condensed practical notes. The present volume has in all nearly 4,000 articles and items (40 for a penny!) The next volume will be like it, "only more so."

Hints on Sending Money.—Some persons still need to be reminded, in sending money:—1st, To state how much money is enclosed, and tell plainly and briefly just what it is for. 2nd, To see that the amount is *actually* enclosed. 3rd, To put business and editorial matters on different pieces of paper, with the name, date, and place on each. 4th, To always give both the Post-Office and State. 5th, To seal firmly and direct very plainly. Attention to these points will save much trouble and ill-feeling. In our experience, not one letter in ten thousand is miscarried, nor does a mistake occur any more frequently, when the above directions are followed.

Good Premiums.—We again invite attention to the list of good premium articles on page 377. We are already sending a large number of these articles to persons who have secured them thus early, and there is plenty of time and room for others to get them. The supply is not limited, and there is no competition, except where two or more persons in the same neighborhood are each trying to get up a list first. Of course they can all get premiums in proportion to the number of names sent by each. Churches and schools are moving in the matter of getting melodeons; farmers' clubs are working for libraries, and many are at work on their own account.

Strawberry Plants for ALL.—A canvasser for a premium writes, that some of his club ask "what will be done with the extra 5 cents required, if their names arrive too late for plants?"—*Answer:* No one will be too late. We shall keep on propagating and distributing the plants, until every subscriber for 1864 is supplied who applies for them, and provides for the postage and packing (5 cents). It is merely a question of time. Those names already in, and many thousands more, will certainly be supplied in time to get the plants well started next season, and we expect this will be the case with all. Those applying last will be supplied last—perhaps some of the latest not until the following Spring; it will depend upon the weather next season, but *all* will be supplied as soon as possible. The plants will be sent out in the order in which the names stand on our books. These plants are not given as premiums for getting subscribers, but are offered to all on the same terms.

A Word to Advertisers.—It is necessary to repeat to persons who have not seen our previous notices, that we cannot take any business cards, at any price, for secret remedies, except in special cases, and then we must be informed of their composition and know this to be good. Advertisers unknown to us personally, or by reputation, must furnish references. Our rule is, to advertise nothing which we would not advise a brother or nearest friend to purchase, if in want of anything of the kind; and to admit no advertiser whom we have not good reason to believe will do just what he ad-

vertises to do. Advertisements must come in before the middle of the previous month to be sure of insertion. See the terms on page 378. These strict rules are needed and adhered to, not only for the protection of our readers, whom we desire to treat as if members of our own family, but also to protect good men, who of course prefer not to have their announcements placed among a lot of promiscuous advertisements of all sorts—good, bad, and indifferent. Considering the selection made, the character of the paper and style of printing, the length of time each number is in the hands of the readers, and the large circulation (90,000,) we are sure our terms are lower than any other journal in the world. We do not specially solicit advertisements—more than enough for all the space we can spare are usually offered. We of course are thankful for a moderate number of good business announcements, as these materially help out the finances in these times of high prices.

To Inquirers.—Numerous letters come to the *Agriculturist* office asking about matters of interest only to the writer. Questions upon subjects where the answer will be of general interest and will convey useful information, we are happy to reply to. It would not be just to the rest of our readers to occupy the columns of the paper with replies to personal queries. Persons who write upon matters of private interest should at least provide for the postage on the answer. Just now, certain so-called doctors are flooding the papers with their advertisements, and we receive numerous queries as to the standing of cancer and other special doctors. It is a safe general rule, to conclude that the physician who can not get patients, save by parading his wonderful cures in the papers, is not a man of remarkable skill. A physician who has a proper regard for the dignity of his profession, never publishes certificates of his cures. It will save our readers the trouble of writing, and us the trouble of replying, to recollect that we can not recommend doctors of this sort, the different "sure cure" medicines, nor the various "beautifiers of the complexion."

The New Sunday School Book. ("Lessons for Every Sunday in the year, No. 2,") was issued Nov. 21, and all copies previously ordered sent off soon after. This book has been prepared with great labor and care, and is doubtless free from the typographical errors occurring in the first edition of No. 1. It will be found very complete, and full of information, and it seems to be just what is wanted in every Sunday School, and in families as well. No. 2 may be used after No. 1, or entirely independent of it. The copyright of these books was given away to others, but editions are prepared for the Publisher of the *Agriculturist*, who will supply them at a price hardly covering cost at the present value of printing paper. They are both well bound, contain 112 pages each, and are supplied by the single copy, or in quantity, at 10 cents each. If to go by mail, the postage, to be pre-paid, is 3 cents each copy in packages of ten or more. The postage being rated by the 4 ounces, the price for less than ten sent by mail is:

1 copy, 14 cents.	4 copies, 52 cents.	7 copies, 90 cents.
2 copies, 23 cents.	5 copies, 66 cents.	8 copies, 104 cents.
3 copies, 42 cents.	6 copies, 80 cents.	9 copies, 118 cents.

Send your Name.—Money for books has been sent from Reading, Pa. No signature to the letter, and we are without clue to the owner. The same occurs in another letter, containing \$2, from Terre Haute.

Clothing for Children Wanted.—We have received an earnest appeal from the New-York "Children's Aid Society." The Association provides for a large number of homeless children. The wardrobe is empty, while clothing is needed to dress the children for sending to the West, and to enter the city Industrial Schools. Any common clothing will be very acceptable—"shoes, socks, coats, and pants, frocks and underclothes. Old clothes can be used to much advantage." Bundles sent for, if address be given, to J. Macy, Assist. Secretary, No. 11 Clinton Hall, Astor Place, N. Y. city.

A Lot of Humbugs.—Never before have we known so many schemes in operation to filch people's money. We have written item after item (see pages 359 and 363) supposing each would be the last needed, but every day brings to light some new swindling enterprise, and by the time the paper gets well to press, others will be discovered. We will group a few together here:—One advertises \$4 for \$1, in gold pens, books, etc., at 186 Broadway. There is no such number. John Street cuts through between 154 and 192 on the east side. So the dollar we sent down there to try the scheme, came back. We did not conclude to send it to the Post Office as invited, for we like to see into whose hands our money goes and what we are to get for it. At another place we did not conclude to invest in Gold Lockets, Watches, etc., advertised at "half price," though we could not positively

say the party would return no equivalent for the money so earnestly solicited *by mail*. Gold is gold, and silver is silver, in these days, and nobody has any to give away at half price.—"Zissino & Co.", (of Philadelphia we believe) send tickets right along with a very honest looking circular, marked "Private—To Agents." We advise that no one invest money there, unless he can *carry* it, and get the great prizes offered when he planks down the cash. If any one can get, in hand, the great amount of jewelry, and *know* it to be genuine, and if he wants it at the price, we have nothing to say.—If anybody for one dollar can get a weekly paper for a whole year, and also a grape vine, just such as anybody else can get but must pay \$2 for; and the said vine is known to be alone worth two dollars, it will do to invest, for it don't matter whether the paper is kept up a whole year or not, nor whether it is worth more than so much waste paper, when it is got.—"Prof. Weslook, Box W, No. 175 Bleecker Street, N. Y. City," (a private boarding house!) advertises two swindles at a dollar each. We sent the \$2 to catch him, but after various excuses, he told our young man he could only get the articles through the Post Office! We have handed him over to Mayor Opylke, also.

In Writing to Advertisers for circulars, or otherwise, it is well to tell them where their business cards were seen; they are always glad to know where their announcements are noticed, or through what channels they reach the largest number of wide-awake readers.

New Book for Sheep Raisers.—S. Randall, LL. D., whose *Sheep Husbandry* at the South, published in 1848, and whose essay on fine wool sheep read before the N. Y. State Agricultural Society last year (1862) have caused him to be recognized as authority on Sheep, is again before the public as the author of a comprehensive work, adapted to the wants of American farmers—entitled *The Practical Shepherd*. It is a 12mo. of 454 pages, fully illustrated. We esteem the work highly and while recommending it to our readers, regret that it is not yet in the market, but for sale only by traveling agents. D. D. T. Moore, Rochester, is the publisher, and its appearance at this time is opportune, for there is now a great interest in sheep culture. The policy of confining its sale to agents is hardly advisable, for thousands would obtain it through regular channels, who will not be found by agents. When we can get a supply it will be announced in our book list.

The Illinois State Horticultural Society holds its Winter session at Alton, December 15, to last 4 days. The meeting will doubtless be a good one, and all interested in Horticulture are invited to attend.

The "Report" of the Department of Agriculture for 1862, is a book of 632 pages, far better than any of the previous annuals on Agriculture, issued at Washington. It contains many pictures of cattle, sheep, and horses, of fruits and insects, poultry-houses, etc., is excellently well adapted to the purpose for which it was made, namely, for an attractive and instructive volume for members of Congress to send home to their friends. It does not comport with the dignity of the Government to put forth a picture-book, nor one for the purpose above stated. Many subjects are well treated, the articles being a little more extended than would ordinarily be published in an agricultural Journal. Those on sheep, considering the great interest now awakened in sheep-raising, will give the book especial value with a great many farmers. We do not think this is the place for descriptions of a few old and well-known fruits, most of which are as well or better described in the fruit-books, nor for an essay on marbles, building-stones, or coal-oil springs, which are hardly agricultural topics.

Book on Fruits.—Alfred Street, Middlesex Co., Canada. Barry's Fruit Garden, is a very good work on the culture of Small Fruits. See our book list.

Books out of Print.—There are several orders on file for agricultural books which have not been filled, for the reason that the works are not to be had. Where there is a prospect of a new edition being ready soon, the money is placed to the credit of the sender, and the books forwarded as soon as issued.

Osage Orange Hedge Plants Wanted.—Tobias Martin, of Mercersburg, Pa., wishes to secure 50,000 to 100,000 plants. Who can supply him and other inquirers?

"Smith's Canterng Horses."—One of these, which came to our children as a "Christmas Present" in advance, has proved a very acceptable and interesting gift. Some "grown up children" enjoy a ride occasionally, and the horse manifests no signs of weakness under the load. His rations are not expensive.

Chloride of Lime.—Explanations.—

This is recommended in some papers as a manure, and we are asked how it is used to dry the atmosphere in fruit-rooms, without imparting an odor. In such cases the article usually known as chloride of lime (bleaching powders) is not intended at all; here, as in many other cases, a misuse of chemical terms may lead to an unpleasant mistake. When lime and salt are employed for agricultural purposes, whatever decomposition takes place produces *chloride of calcium*, which is the *chloride* of the metallic element of which lime is an *oxide*. When chloride of calcium has all the water driven off by heat, it absorbs moisture again very readily, and this is the material used in France to destroy the humidity of fruit-rooms. The chloride of lime is a common name for a rather complex substance containing several chemical compounds, besides a quantity of free chlorine. It is employed as a disinfectant and for bleaching, but not for either of the purposes above alluded to.

Sheep Washes.—

A number of these preparations are used in England, and one is now advertised in our columns. As a general thing, we refuse to advertise secret preparations, but the composition of this being made known to us, we should think that it would be certain to destroy vermin, and be beneficial in skin diseases. The certificates of reliable men who have used it would seem to warrant others in making experiments with it.

Persian Insect Powder.—

P. A. Bertens, Florence. This is the powdered flowers and leaves of *Pyrethrum Willemoti*, and probably other Caucasian species. The powder was first introduced, put up in small bottles, as a secret preparation, but it may now be purchased in bulk at some of our city drug stores. It readily stupefies most insects, and if the application is thorough, kills them. The powder should be kept in well closed bottles, otherwise it loses its power. The article has become one of considerable importance, and the inhabitants of a number of villages in the Caucasus devote themselves to its cultivation and preparation. It has been introduced into France, but we have not heard of its being grown in this country.

Sweet Potatoes and Yams.—

L. Kesinger, Buffalo Co., Wis., asks if these will succeed in his State. We have a letter from a correspondent who says he has been successful with the Sweet Potato there. If by Yam he means the *Dioscorea Battatas*, we suppose that it will grow there; it is perfectly hardy here, and difficult to eradicate when once it gets a foothold in the soil.

Buying a Farm on Credit.—

"A Friend" asks of the *Agriculturist*, whether it is advisable for a man having \$300 cash, to buy a farm for \$3000. Decidedly not, unless you know of a gold or other mine on the premises from which a large amount of the price can be speedily dug. As a rule, it is seldom safe to run in debt for more than one half of the purchase money, and many have found even this a heavier load than they counted on.

A "Water Gap."—

"Young Tennessee farmer" asks how to make a good permanent water gap. Perhaps some reader of the *Agriculturist* can tell us what it is, and him how to make one. It is probably a local appellation for something others know by a different name.

Straw Beehives.—

To "Black Brook's" inquiries about the straw hive described in the *Agriculturist* for October we answer: There is an entrance for the bees at the bottom of one end, three-eighths of an inch high by three inches long. It will admit all the air the bees need through the winter. Any good straight, clean straw is suitable, and probably flags and rushes would do. Oat straw looks rough, but answers well. Rye with the heads trimmed off, makes a very neat hive. For cutting the straw, the old-fashioned primitive straw-cutter is probably best. One is needed that will allow the straw to be pushed through the proper length. It is unnecessary to wash the hive with any thing before admitting the bees.

Grafting the Shag-bark Hickory.—

"J. S. H." Marlboro, Mass. This is sometimes done in the South of Europe, but it is said not to succeed well in cold countries. Flute or ring budding is said to do best. Walnut trees are very difficult to transplant at any time on account of their few fibrous roots. We should prefer Spring for the experiment.

Three Crops of Pears in one Year.—

"E. N.," writes that there is a pear tree in Evansville, Ind., which produces two crops of pears in a season, and this year bore three crops, two of which came to perfection. It is not rare that pears set fruit for the second time, but such fruit is usually inferior, if it ripens at all. It is not a desirable character in a tree.

Distance for Dwarf Pears.—

J. C. Cole, of Chautauqua Co., N. Y., writes that he set his pears at 6 feet apart and finds them too much crowded. It will do to move them in the Fall or Spring if done with care. Pears may be so pruned as to be kept at this distance, but we think it better to give them more room, 8 or 9 feet is near enough for the free growing kinds.

Grape Vines on Walls.—

"Subscriber," who has a superabundance of stone, in a rocky part of Rhode-Island, wishes to know if it will do to train grapes against his stone walls in place of a trellis. In this country the European practice of growing wall fruit is not practicable. The sun here is so powerful that the leaves and fruit are scorched, and this takes place even where the vines are set too closely to a common board fence.

An Enemy to the Vine.—

G. L. Morris, Baltimore Co., Md. The caterpillar is the larva of the *Satellitella Hawk-moth*. They are great feeders, and are very destructive to the vine, but fortunately not very numerous. They enter the ground after they are full grown, where they undergo their transformation, and come out in the following June and July, as a night flying moth known as *Philampelus Satellitella*.

What is "Wine"?—

It is the pure juice of the grape, which has undergone the vinous fermentation. The addition of sugar, water, milk, eggs, etc., to say nothing of logwood, brandy, alcohol, or sugar-of-lead, makes compounds which may make medicine, but not wine. The juices of other fruits, of rhubarb, sugar and water with a little ferment, the sap of birch and maple, and other things fermented, have more or less a wine-like taste, and may be called wines, but they are not, and as soon as we admit that any thing but the pure juice of the grape is wine, we are all adrift. An old German vintner's opinion was asked in regard to one of these sugared compounds profanely advertised "for Sacramental use," with the assurance that it would not make any body drunk. "No," said he, "it will make you sick though."

New-Rochelle Blackberries Pro-

ductive.—F. W. Winship, Bureau Co., Ill. writes: "In the Spring of 1861, I set out 12 roots of the Lawton Blackberry on the east side of a high board fence. They made a fair growth during 1862, as it was a wet season. I gathered the first ripe berries on the 6th of July, and the last on the 12th of September. One stalk had on it 1400 berries at one time, and commenced to ripen its first berries about the 21st of July, and finished on the 12th of Sept., at which time I gathered 182 ripe berries. Some of the berries from this bush measured 4 inches in circumference, and 10 berries laid in a line so as to touch one another, measured 1½ inches. The stalk was about 11 feet in length, and had 15 lateral branches. From the 12 original bushes I gathered about 3 bushels of berries. Who can beat this, and who says the Lawton Blackberries are not productive?" [The proper name is New-Rochelle, though the same variety is sometimes called Lawton—a name given without proper authority. The general complaint against this variety is its sourness—a prejudice resulting from picking the fruit as soon as it is black; it is not ripe until some days after coloring.—Ed.]

Cranberries from Seed.—

E. T. Baxter, Tuscola Co., Mich. This method of raising plants is not recommended by cultivators, as the plants are very slow in growing, and there is no certainty that a large proportion of them will bear well. If disposed to make a trial, cut the fruit crosswise, when the seeds may be easily taken out; these are to be sown in a patch of moist, well prepared soil, and covered very thinly. It will save much time to get plants from a fruitful bog, or to procure them from some of the experienced cultivators.

Small Fruits in the Shade.—

J. B. Jones, Hudson Co., N. J. Blackberries and especially Raspberries do well in partial shade. Strawberries require more sun. Currants will grow tolerably in a little shade.

Names of Fruits.—

I. M. Chapman, Portage Co., Ohio, wishes to know how to pronounce *Triomphe de Gand*, and objects to such "outlandish and barbaric names being applied to fruits, etc." *Tree-omph der Gan*, is as near as we can give the pronunciation in English. The strawberry originated in Gand (Ghent) and the name means the triumph of that place, and sounds not strangely there. The name is generally pronounced *Triumph de Gand*, in this country, and might conveniently be shortened into simple *Triumph*, in the same way that the Duchesse d'Angoulême is now abbreviated into *Duchess*. A Frenchman would be as much troubled at some of our names, Hubbardston Nonsuch for instance, as our friend is at that of this strawberry. When new things are brought into a country where a different language from the one in which they originated is spoken,

their names, if the things themselves become popular, are soon popularized. Such names are not "barbaric"—they are only unusual.

Plants for Names.—

"H. J. L.," Fairfax Co., Va. The plant is *Gentiana Saponaria*, the Soapwort Gentian.... R. S. Reeves, Logan Co., Ky., sends a narrow-leaved variety of the same species; variety *linearis*. *Gentiana angustifolia* has only one flower on the stem. J. A. Brown, Wayne Co., Ohio: The seeds sent are those of *Fraseria Carolinensis*, or American Columbo, the bitter root of which is used in medicine as a tonic, and is sometimes sold instead of the imported columbo.... Angelo Brown, Wayne Co., Pa. The hardy annual is *Erysimum Pereffskianum*; it came from the Caucasus, and is a species of Hedge-Mustard.... T. C. Wells, Riley Co., Kansas, sends *Dalea laxiflora*, a pretty perennial from the prairies. Those who send specimens are requested to give their address in full, as we sometimes wish to make inquiries.

Yellow Lupin.—

"Reader," Pine Plains, N. Y. We have not heard of any experiments with the Yellow Lupine. The White Lupine has been tried, but without much success. The difficulty with the Lupines as a green manure, seems to be that the seed is so large in proportion to the amount of foliage produced that it takes an enormous bulk in comparison to clover.

Thorns from Seed.—

T. Wilbur, Marion Co., Mo. Gather the fruit when it is dead ripe, put it in a vessel of water until the pulp becomes sufficiently softened to allow the seeds to be separated, and then wash them out. Sow at once if the ground is open, or mix with earth in a box and expose to the weather during winter, and sow in Spring. Some species of the thorn do not come up until the second year after planting. We do not know how the Black Thorn is in this respect.

Osage Orange Seed.—

Several Subscribers. We have to repeat what we have already stated several times, that we do not know where the seed can be procured. The supply formerly came from Texas, and other States now in rebellion. Seed is produced in the loyal States—but not at all enough for the demand—Now that the commercial supply of the seed is cut off by the war, those who have bearing trees are turning their attention to saving the seed from them, and we have several inquiries as to how it may be secured. The fruit is placed in heaps until it has decayed, the seed is then washed out and dried. It is better to expose it, mixed with sand, in boxes, to the action of frost, as it is then more certain to come up promptly in Spring.

Allen's Cylinder Plow.—

O. Kimmet, Sibley Co., Minn. Allen's Cylinder Plow is not made of steel. He has steel plows adapted for use on the prairies, at prices from \$10 to \$13; it may perhaps be cheaper for you to purchase one from some house nearer home.

Lightning Rods.—

R. D. Warren, Mass. Never having seen the copper rod of which you speak we can not express any opinion. As copper conducts electricity about five times more readily than iron, it has an advantage over that metal, as the rod can be made much smaller than usual, and be equally efficient.

Unreliable "Cures."—

How many of the vaunted "cures" of animals of one trouble or another, are really due to the applications made by the would-be doctor? Very few, we apprehend. Give ailing animals good care, a loosening diet if needed, with protection from the weather, and in nine cases out of ten they will get well themselves. Nature will often effect a cure in spite of all manner of malpractice, which is subsequently regarded and heralded as the means producing the cure.

Cheap Paint for Brick Walls, etc.—

Mix hydraulic lime (cement or water lime) with water to the consistence of thin cream, and apply it with a brush like a lime wash. The color which is a pretty stone color, may be varied by using any of the ochres, lamp-black, etc. It will not hold upon wood.

Removing the Hair.—

A lady wishes to know if there are any means by which superfluous hair can be removed from the hands and face. Several preparations called "depilatories" are sold; but, so far as we have any knowledge of their composition, they contain arsenic, lime, or some other caustic, unsafe to the skin. A less dangerous but somewhat painful method, sometimes used in surgical operations, is to cover the hairy spot with adhesive plaster, leave it on a few hours, and then remove it with a smart twileh, which will take out many of the hairs from the roots—if not all of them. Most of the depilatory operations are of only temporary effect.

Seaweed as a Manure.—S. Coates, Washington Co., R. I. Seaweed is most economically applied as a compost. Your proposed plan to decompose it with lime and soil or muck, is the right one. The gelatinous sorts like Ribbon-weed, Rock-weed, and Devils-apron, are the most valuable, while the eel-grass, which is frequently called seaweed, is worth but little. The report upon the geology of your State has, if we recollect rightly, some interesting matter upon this subject.

Ashes of Leaves.—"Will the leaves of the same plant, grown in different soils, contain in their ashes different proportions of any earthly materials which may be abundant in one soil and scarce in another?" inquires W. H. Washburn, Waldo Co., Me. The ashes of the same plant grown under these different circumstances, are very similar, but important differences may sometimes be noted, and these are particularly observable in the leaves. Still the ash of the leaves will not necessarily contain "any earthly materials which may abound" for clay at least is not taken up by the roots. Other things may also be rejected. The proportion of potash and soda, of lime and magnesia, and of oxide of iron, silica, phosphoric and sulphuric acid, and chlorine may and do vary.

Tobacco.—"J. B., of Pleasant Valley Mills, near Staunton, Newcastle Co., Del., writes to the *Agriculturist* about some very fine leaves obtained from Cuba seed, and his fine crop generally. He says his system of culture is very different from the methods given in the prize essays published by the *Agriculturist*, and described in other works. Any new method should be well tested a year or two at least, before giving it to the world. One can not judge of his success before the crop is cut, cured, and weighed. The use of any process of culture which would make the labor less by doing away with the necessity of thoroughly enriching, working, and weeding the soil, would be most unfortunate, for it is in these that tobacco culture is of any real value in our agriculture.

Kentucky Blue Grass.—J. L. Woodbury, Kent Co., Del. Kentucky Blue Grass makes good hay, but the yield is much less than with Timothy or Red Top. It has the disadvantage that it is a long time in making a dense sward. It is more valued as a pasture than as a meadow grass. Experiment only can determine whether it will do better than Timothy with you.

A Good Crop from an Acre.—M. Allen, of Columbia Co., Wis., writes to the *Agriculturist*: "I have on one acre raised 5370 pounds of ears of corn, equal to 74 bushels of shelled corn; 800 pumpkins, 8 bushels white beans, and a few turnips on the same acre. Corn worth 50 cts. per bushel, \$37, beans rated at \$16, pumpkins worth \$8, making a total of \$61. No extra preparation or care. Can New-England do better?"

Union Sweet Corn.—An ear of sweet corn having the national colors, red, white, and blue, in the kernels, has been placed on our exhibition tables. It was raised by Col. Sylvester R. Hazard, of Newport, R. I., a veteran of the war of 1812. Such specimens are the result of a mixture of varieties, and can not be depended upon to reproduce the same assortment of colored kernels.

Popular Chemistry.—There is a great deal of nonsense to be found in agricultural and other papers, which passes for science among those who are ignorant of chemical facts. As an illustration of this we cite directions for making a tree wash which appeared in a paper edited by a "professor." "Heat sal-soda red hot in an iron vessel; to do this the vessel should be imbedded in, not over a hard coal fire; this will drive off the water and carbonic acid which it contains, rendering the soda caustic." We should like to see sal soda rendered caustic by heating in an iron vessel. Every one who knows any thing about chemistry knows that this can not be done by the action of heat alone. The water is driven off and when the heated soda is dissolved to make the tree wash, the solution will be precisely the same as it would have been if it had not been heated.—Another exchange commenting on the use of salt as manure remarks that "in the vicinity of salt water the lands are salted by the dews which fall." Will he please procure a small bottle full of this salt dew for exhibition; scientific men would hail it as the most remarkable discovery in meteorology.

Detection of Water in Milk.—The manager of an extensive cheese dairy in New-York consults us in regard to methods of testing the purity of milk. He uses two lactometers, neither of which he thinks "will detect the presence of 1 gallon of water in 20, 40 or 80 gallons of milk." That is, neither will show 5 per cent of water which is 1 gallon in 20 (1 gallon in 80 is only 1¼ per cent). Of course not. The specific gravity

of good milk is about 1.031 to 1.032; that of milk rich in butter, is 1.030 to 1.031, and the addition of 10 per cent of water will reduce the specific gravity of good milk only to about 1.029; 20 per cent to 1.025, or near it. Different samples of pure milk often show more variation in their specific gravities than 5 per cent of water added to either would effect. The only way to judge accurately of the value of milk brought from various sources is to have some man or woman of good judgment devote him or herself to the study of the different samples, testing, and noting down every day the character of the milk from each dairy. Noting 1st, the cleanliness; 2nd, the specific gravity; 3d, the length of time, before souring; 4th, the amount of cream, and its character, setting about a gill of each sample for these purposes; 5th, the color of the skim milk; and 6th, if sweet, its specific gravity. Thus those who furnish the milk can each be credited according to the quality of that furnished.

Prolific Hens.—People always like to compare notes about poultry. J. B., of New Castle Co., Del., says, six hens costing \$2.50, placed in an empty hog pen, fed on scraps from the table, egg shells, etc., with the sweepings of the mill floor, gave 497 eggs and 8 chickens in 172 days. He estimates his only outlay \$4.37, including 50 cents deterioration on stock. The eggs were worth 19 cts. per dozen—\$7.86. The chickens at 20 cents each are worth \$1.60, and the manure made is worth 18 cents (estimated too low)—in all, \$9.64. Subtracting cost, \$4.37, leaves \$5.27 profit in less than 6 months.

Damage to Sheep in Ohio.—36,778 sheep are reported killed by dogs in the year 1862; 24,972 injured, and the total damage estimated at \$126,347. Will any body tell us how much good was done by all the dogs in Ohio, during the year 1862? Also tell us what the boarding bill of these dogs amounted to.

Ants and Bees.—A writer in the Rural New-Yorker in directing how to get rid of ants from beehives, advises to blow smoke into the hives, which will expel both bees and ants, and then with a feather apply spirits of turpentine or kerosene to the places where they have harbored, which will keep them away. He forgot to add that bees also are very sensitive to unpleasant smells, and that they too would probably stay outside the premises, if they could not immediately cover over the infected parts that the odor would be suppressed.

White Flax Seed.—John Monteleiu, Stephenson Co., Ill., informs us that he once purchased some bushels of this variety, and that more or less of it has been raised in his vicinity for eight years. He can discover no difference between this and the brown seed either in the fibre or the oil.

What can be Done on Scrub Oak Land.—Mr. Wm. Erwood, an English gardener, who 8 months ago cleared up some scrub-oak land upon Long Island, has sent to the *American Agriculturist* Office specimens of his products, comprising fine Brussels sprouts, good cauliflower and collards, and onions of full size. Mr. E. states that he has fine potatoes and corn, and is altogether pleased with his attempt at making a farm in such an unpromising locality.

A Good Suggestion.—E. G. Topping, Whiteside Co., Ill., says that every farmer should keep on hand a supply of hoop iron and rivets, which can be procured at almost any store having an assortment of hardware. It requires but a few minutes work to replace a hoop from a cask, pail, or tub; and this if done in time, will often save the purchasing of a new vessel.

Queries About Trees and Shrubs.—L. Kessinger, Buffalo Co., Wis. The *Crataegus coccinea* of this country is not the same as the European Medlar. The objection to the use of our native thorns as hedges is the early fall of their leaves. Where this is not a consideration they will answer. The Persimmon does not succeed much north of New-York city. It is hardly probable that it would do well with you. We think that the Mulberry is hardly enough to stand your climate—at any rate we should try it. We know of no peaches that are likely to be successful in your locality.... I. F. McLain, Morrow Co., Ohio. The soil for Osage Orange should be well pulverized by deep plowing. If sod ground is used, the sod should be broken up and left to rot. The planting is generally done in the Spring. The plants are cut back to 6 or 8 inches, and the roots are trimmed. The hedge is not trimmed the first year, but the second and following years it is brought into shape. It requires about four or five years to form a perfect hedge. We have not space for details which have already been given in former volumes of the *Agriculturist*, and may be found in Warder's Hedges and Evergreens which is on our book list.... D.

P. Leonard, Washington Co., Ohio. Locust seed may be planted as soon as gathered, or be kept until Spring in boxes of earth exposed to the action of the weather. The seed bed should be of good soil, well prepared, and the seeds sown thinly and covered over half an inch deep. The plants will grow from 2 to 4 feet high the first season, and can be transplanted after the first year's growth.

Propagation of Forest Trees.—"T. C. H., Pleasant Plains, N. Y. Cions may be cut any time during Winter, and treated like those of fruit trees. The Hickory has such long tap-roots that it is difficult to transplant; the seed should be planted where the tree is expected to stand. The Chestnut may be removed more readily, and small trees from the forest may succeed, but the only sure way is to get or grow seedlings which have been several times transplanted.... Mildred Luther, Boone Co., Iowa. Mix the Red Cedar berries with earth and leave them in an exposed situation, where they will freeze and thaw during the Winter. Sow when the ground is ready in the Spring. They sometimes remain a year in the ground before they start, but treated in this way there is more probability of their growing the first season.... Thos. Bell, Joe Davies Co., Ill. White Birch and White Maple seed, as soon as it is gathered, should be mixed with sand or moderately dry earth, as without this precaution they get too dry, and lose their vegetative power. Prepare the surface of the seed-bed by burning rubbish upon it, to destroy the seeds of weeds, and cover the seeds very slightly after sowing. To prevent the soil from drying, a light covering of litter is to be thrown over the bed, to be carefully removed as soon as the young plants begin to come up.

What Trees to Plant.—Harry Grundy, Montgomery Co., Ill., asks what trees he shall plant about his house. Advice of this kind is very difficult to give without knowing the character and climate of the locality. As the maple grows with Mr. G., we presume most of our hardy shade trees will do well. It is well to plant both evergreen and deciduous trees. For evergreens, the Red Cedar and Norway Spruce. Instead of putting out only one kind of deciduous trees, we should select a variety, not only as producing a more pleasing effect, but for the reason that disease or insects frequently attack all the trees of a particular kind within a large district. Having a variety of trees will often save one from great disappointment. The American maples, the Sycamore Maple, Elm, Whitewood, and Buttonwood, would probably all flourish, and give a variety.

"Responsible Nurserymen."—C. O., Hendricks Co., Ind., pertinently says that we recommend planters of trees to "send directly to some responsible nurseryman" for them. He followed the advice and sent, and obtained from "a nurseryman of large business, and reputed honesty and responsibility, badly grown and almost worthless trees." Now he says: "I insist on the purchaser selecting his trees, etc., personally." So we have often advised, to always do when practicable; but it is not always possible, and we must trust somewhat to the nurserymen. There are few men in the world who will cull out from their nursery rows the most saleable trees to send to a stranger. If he comes cash in hand, and makes the selection himself, it is a different thing. Still, there is no excuse for sending a poor lot of trees or vines, when a first class price is charged.

Pears in Illinois.—Jabez Webster, of Marion Co., Ill., writes that "pears suffer much from blight in his neighborhood. The Bartlett does best, and the Howell next, but this year even these have suffered. The Vicar of Winkfield grows well, but does not bear as a dwarf or standard. The Tyson, Beurre Giffard, Louise Bonne, and others on quince, neither grow nor bear. Bartlett, Vicar, Flemish Beauty, and Osband's Summer do much better as standards without manure than they do as dwarfs with manure." Mr. W. says that "dwarfs are about 'played out' thereabouts; people begin to open their eyes to the fact that they are not enough adapted to the climate to pay for the labor and trouble, while standard trees will flourish as well as apple trees and come into bearing as soon."

The Penn Pear.—The Rev. A. R. Buel, presented us with two specimens of this pear, which has also been known by the names of Frazer and Railroad Fuss. The latter name was given because the original tree was the subject of some difficulty at the time the Camden & Amboy R. R. was made. It has been called Penn, because it originated opposite the old Penn estate. The shape of the pear is remarkable, it being very much depressed and broader than long. Downing classes it as "very good." The specimens were tested at the fruit growers' meeting and hardly warranted this endorsement, probably because they had not been properly ripened.

Good Catawba Grapes.—The finest Catawbaws we have seen this year, were a box of some 25 lbs. presented Nov. 6th, by Josiah Carpenter, Commission Merchant, whose business card has long been in our columns. They were grown on lattices, by J. Larowe, of Hammondsport, Steuben County, N. Y., which must be a good locality for this uncertain variety, judging from the well ripened, large clusters and berries. Mr. C. says he has had them from the same place through the Fall, and they have sold higher than any other Catawbaws in market. They come packed in neat, light, board boxes, 24x10x5½ inches, with a division across the middle. The ends and division boards of ½ inch stuff; the rest ¾ inch thick. White wrapping paper is placed above, below, and between the layers. *Query:* Would not small air holes preserve the fruit longer?—A few bottom clusters, slightly mashed by hard handling, were a little sour.

Cold Grapery.—B. Ayers, Rock Spring. The interior is usually painted white, but in this country there is no objection to coloring them any pleasant tint. Light stone color makes a good contrast with the foliage.

Croton Point Isabellas.—Dr. R. T. Underhill sent us some very large Isabella grapes, rather larger than usual even from his vineyards, but hardly as sweet as in some previous years. The uncertainty of this variety in many localities, and its inferiority in flavor to some of the newer grapes, are not in its favor, though Dr. U. is still successful in supplying a very large amount of grapes to a multitude of persons in New-York who would otherwise be unable, as yet, to eat grapes at all. Some assert that his example has retarded grape culture generally, as so many have been led by it to go largely into the culture of the Isabella, with poor results. On the contrary, we suspect the noise made about his grapes, and the reported profit of his vineyards, have done much to awaken an interest on the subject, and if this leads to a larger culture of better varieties than the Isabella, good will come of it.

What Grapes to Plant.—"Onondaga" asks for a list of twelve sorts for family use. We do not know of that number of good grapes which have been sufficiently tested to warrant a general recommendation. The list given on page 325 (Nov.) includes seven sorts, and some of these are put in as only promising well. If disposed to experiment, we should add To Kalon, Anna, Elsinburgh, and test the newly-introduced Iona, Israella, and Adirondack. Unless one wishes to buy experience, it is best to plant only a few sorts which have been thoroughly tested. Hartford Prolific, Concord, and Delaware, will make a long season, and are reliable. When we know more of the Creveling, we may be able to put it in place of the Hartford. It promises well, but has yet to stand the test of extended cultivation.

Grapes for Canada.—R. M. Goodman, Ohama. The Delaware, the best of our native grapes, is hardly where any grape will grow. The Clinton, only a fair quality, is also hardy. The Oporto is not a good table grape, and is less suited to high latitudes than these.

"Caper Tree."—A lady at Hampden, Me., says she has a caper tree, and wishes to know how to make pickles of the seeds. The true caper is a shrub, and is not hardy in this country. The imported capers are the unexpanded flower-buds, and not the seeds. We cannot guess what the tree can be.

Hawthorn Hedges.—Charles Elliott will find a portion of his questions answered in another item. The plants are set at a distance of 6 inches if in one row; or a foot apart if in two rows, and the plants alternating, i.e., those in one row set opposite the spaces in the other.

Oregon State Fair.—Many Eastern people, who remember how recently the Flathead Indians came from beyond the Rocky Mountains in search of the White man's Bible, can hardly appreciate the fact that Oregon is already a flourishing State, with all the institutions of the older States in full operation. The Pacific Christian Advocate, published at Portland, reports the Oregon State Fair as a "fixed fact," the one this year exceeding any of its predecessors. There was the usual display of agricultural and horticultural products, of manufactures, household articles, etc., and the modern inevitable "agricultural" horse-racing. A yearling heifer, and a two-year-old bull, of the Durham breed, indicate that blooded animals are not overlooked. The Fair lasted five days, and was visited by about 10,000 persons! Military companies, and bands of music were present in large force, and were a marked feature of the occasion. The Advocate mentions one note-worthy fact, viz., "the order observed was excellent; we did not see a single drunken person, and heard but a single oath, though we mingled freely among the multitude present."—We bid

our distant friends good-speed in their efforts to improve the agriculture of the new State, and we hope the many hundreds of copies of the *Agriculturist* they now receive, increased to as many thousands, will be found an efficient aid in the work.

Measurement of a Ton of Hay.—This is one of those things which are entirely indefinite. No man can tell how much space a ton of hay will occupy in a mow or stack. It depends upon the dryness of the hay, its age, the height of the mow, whether it has been trodden, either at the time it was placed in the mow or afterward, whether the hay has been disturbed or not since haying time, and *what kind of hay it is.* A ton at the top of a stack will measure more than one at the base. In a mow 20 feet high, carried up square to the top, the average will be about 400 cubic feet to a ton—more at top, less at bottom. (See May *Agriculturist*.)

Prairie Seedling Potato.—W. S. Carpenter, of Westchester Co., N. Y., has sent us specimens of this potato, which is a new variety to this neighborhood. He says that the yield is 300 bushels to the acre. The potato is of good size, and quality excellent.

Slugs on Potatoes.—Mrs. Babcock, Hampden, Me. The slug which infests your potatoes is not recognized from the description, and we can only suggest hand-picking, or the aid of a brood of ducks or turkeys.

Tan Bark as a Manure.—D. W. Kinsman, Cheshire Co., N. H. On account of the difficulty with which this is decomposed, it is not highly prized as a manure; it may be decomposed by composting with lime. Its chief value is as a mulch, for which it is applied around the roots of fruit-trees, bushes, and vines.

Fish, etc., on Dry Land.—"Subscriber," asks how fish, frogs, etc., come to be found on land, as occasionally happens. Usually they are drawn up by a whirlwind, and fall when the wind subsides. Sometimes a single one, "alive and kicking" like the one described in his note, is dropped by some bird of prey. They do not "generate spontaneously" in the clouds.

Sex of Eggs.—A "friend of the *Agriculturist*" writes from Blue Point, that when he wishes a brood of males he selects the longest eggs he can find, and if females are desired, the roundest ones are chosen. He says that he never knew this to fail.

Cheap Sewing Machine "Agencies."—Give them all a "wide berth."—We have investigated some half a dozen and not yet found one to which we would entrust a dollar. Some offer a great discount after the first machine is paid for at full price. A good many have written us that after sending \$5, \$10 or \$15 to some out-of-the-way New England town for a "sample," they could never get any response of any kind. One man ordered a sample machine to be paid on delivery, but the strict orders to the express man were to "C. O. D." (collect on delivery,) and so he paid \$10, and \$5 more for charges, and when opened, the machine was not worth a dollar—even for scrap iron, and no answer can be got to his complaints. That's the way the thing works.

Humbug Mining Companies.—Just now the country is flooded with sundry "Mining Company" enterprises nominally located, or to be located on the Pacific Coast, but of which the real and only location is in some 3d, or 5th story in Philadelphia, New-York, Boston, or Cincinnati. Very attractive are some of the schemes, circulars, blank "Certificates of Shares," etc. Post Masters are especially solicited to act as agents and offered large inducements. Two or three dollars of your money will buy a share that will very soon be worth \$5000 to \$10,000,—all in gold! We should like to make a few such investments if we could, but "we don't see it." We have one of the most taking of these concerns in tow, whose operations we shall be able to show up in full by next month. In the mean time, if any reader will find one of these Eastern Mining Companies, advertised by circulars, which is at all trustworthy, we will pay a large premium for a chance in the enterprise.

The Wine Plant Humbug is still carried on in various parts of the country, as we learn from several letters. For example, Mr. B. F. Brown writes from Dane Co., Wisconsin, November 8, that "an agent is there selling Linnæus Rhubarb at \$37.50 per 100 plants—many of them not the size and length of a man's little finger—telling people that they can make 1½ gallons of wine from each plant next season, which will sell readily for \$2 a gallon; that government agents are contracting for all they can at this time, etc." This is sheer lying and swindling. Neither government agents, nor any body else is doing, or will do any such thing. A plant set now, will not make 1½ pints even of what is called wine,

next season. Reliable men, King and Murray of Flushing, and others have this year advertised in the *Agriculturist*, good Linnæus Rhubarb roots at \$18 to \$25 per thousand (only \$1.80 to \$2½ per 100.) Our previous notice of this matter has probably put upon their guard all our readers except those subscribing recently. Don't believe the stories told, nor trust the samples of real or pretended wine shown. Lastly, try to get the *Agriculturist* into the hands of the multitude of farmers who are being constantly swindled by the thousand and one humbugs. It will save them much money.

Ear Doctors.—If we had a child or friend who had any trouble in the hearing apparatus, we would consult a regular physician, not those advertising; or go to Dr. Geo. Wilkes, (who don't advertise,) sure that he would not charge \$50 to \$500 for telling that there was a little wax in the ear, and how to wash it out; nor hold on to the patient (as long as he has any money) if the case be not curable. Dr. W. charges \$2 for each visit, we believe. His office is at 23 Laight-st. He is President of the New-York Medical and Surgical Society, has business enough, and will doubtless not thank us for this public notice; but we are consulting the interests of our readers, and not his personal comfort. We have not seen him in several years, but we know his character and skill. This notice is needed now—we have just refused an \$800 advertisement of an ear doctor.

Philadelphia Humbugs in California.—Our old college "chum" (Rev. Jas. Rogers) sends us from Downieville, Sierra County, in the Mountains of California, specimens of Humbug circulars issued in Philadelphia, that have been scattered even to that distant point. One of these sets forth a sale (said to be "no Gift Enterprise or Lottery") of \$700,000 worth of Watches, etc., valued at from \$5 to \$250, all to be sold at \$2½ each. The other is nominally from the next door in the same street, offering a beautifully illustrated Journal at \$1 a year, and a gift to each subscriber, ranging in value from \$1 to \$100. We hope these circulars show enough on their face to put people on their guard, yet somebody must patronize the operators, or they would not continue swindling. As the new law allows two or three circulars under one envelope, the operators now generally send out their schemes in pairs, or triplets, under different names, hoping that if one bait does not take another will.

To Remove Coal Oil from Cloth.—"S. B.," of Ontario, Ind. Benzine, now very cheap and largely used in painting as a substitute for turpentine, will remove this and similar stains. In cleaning clothing it should be laid on a cloth folded to form a thick pad, or upon absorbent paper, so that the benzine which has dissolved the greasy matter will be soaked up. The spot should be treated thus several times until it is thoroughly washed out. Merely rubbing the oiled place with a little of the liquid only spreads it.

Why the P. O. Address is not given.—A correspondent thinks it very provoking that we generally only give the County residence of those contributing or making queries in the *Agriculturist*. One of the principal reasons for doing this is, that we may save our readers from annoying correspondence. When it is published that a person has some new or rare plant or other thing, he is immediately besieged by a host of applicants for cuttings, seeds, etc., and we are often requested, on this account, not to use names at all. Swindlers also seize upon all such names. One lady whose full name and P. O. address we happened to give, received 57 circulars within three weeks after.

Pickles for Beef, etc.—E. Montgomery, of Clay Co., Ind., sends the following recipe for 200 lbs., of beef: "Cut your beef in small pieces and pack it in a clean, tight cask. Take 7 pounds of salt, ¼ pound of saltpetre, 1 pint of molasses; put in a pot with water enough to cover the beef, and boil, skimming; when cold, pour it over the beef and put on a weight to keep the beef under the brine." He says he has eaten beefsteaks in May thus preserved all Winter.

An Excellent Meat Pickle for General Use.—To 2 gallons of water add 3 lbs. salt, 1 lb. sugar, 1 oz. saltpetre, 1 oz. potash, boll, skim, and when cold, pour over the meat, which should have been killed two or three days. The amount of salt needs to be increased if it be desired to keep the meat into or through the Summer, or if the meat be packed in Spring. This is excellent for beef for boiling, dried beef, tongues, hams, shoulders, or mutton hams.

Cleansing Old Pork Barrels.—A subscriber, in Monroe Co., Wis., recommends, "After scrubbing, to turn the barrels open end down, and keep a moderate smoke under them for half or a whole day."

Straw Valuable for Feeding.

The following statements, condensed from a report on the above topic by Dr. Charles C. Cameron, to the Royal Agricultural Society of Ireland, are valuable as giving light on a subject which needs further experimental investigation. Dr. Cameron concludes that, pound for pound, the least nutritious kind of straw equals the best varieties of turnips, in its amount of flesh-forming principles, and greatly exceeds them in its proportion of fat-forming elements. He says that straw is more valuable when it is cut in the just ripe state, than when it is permitted to over-ripen, and that green straw contains a far greater amount of nutriment than is found in it even when just ripe. The different kinds of straw are thus ranked in the order of their value: 1. Pea haulm; 2. Oat straw; 3. Bean stalks with the pods; 4. Barley straw; 5. Wheat straw; 6. Bean stalks without the pods. The following table shows the value of Oat straw compared with Meadow hay:

In 100 parts of.....		Meadow Hay.	Oat Straw.
Water	14.61	14.0
Flesh-forming constituents	8.44	5.0
Respiratory and fatty matters	43.63	13.3
Woody fibre	27.16	63.1
Mineral matter, (ash,)	6.16	4.6

In comparing good Oat straw with common white Thrnips, the latter were found to contain but little more than 1 per cent. of flesh-forming constituents, and less than 5 per cent. of fat-formers; while the straw has about 4 per cent. of flesh-formers and 13 per cent. of fat-formers.

As to the woody fibre of hay and straw, experiments made in 1859 by two German chemists, Stockhardt and Sussdorf, prove that cellulose, or the substance in plants of which woody fibre is formed, is capable of being assimilated by sheep and other ruminant animals. They selected two wethers and fed them—1st, upon hay alone; 2nd, upon hay and rye straw; 3rd, upon hay and the sawdust of Poplar wood which had been exhausted of soluble matters with lye, with a little bran and salt added to make it palatable; 4th, with hay and Pine-wood sawdust, bran, and salt; 5th, Spruce sawdust, bran, and salt; 6th, hay, pulp of linen rags (from the paper-maker,) and bran. The experiments were carried on from July to November, excepting a short time during which the sheep were pastured to recover from the injurious effects of the fifth experiment. The animals and their food, drink, and excrements, were weighed daily. The amount of cellulose in the food was determined, and also the proportion in the excrements. In this way it was ascertained that from 60 to 70 per cent. of the cellulose of hay, 40 to 60 per cent. of that substance in straw, 45 to 50 per cent. in Poplar wood, 30 to 40 per cent. in Pine wood, and 80 per cent. in the paper pulp, was digested.

To render a larger portion of cellulose digestible, Dr. Cameron recommends cooking straw. When consumed in an unprepared state, most of its cellulose remains unappropriated. He advises to chaff (cut short) the straw, steam it and mix it with roots and oil-cake or grain; or mix it with sliced roots, moisten with water, and keep it until a slight fermentation sets in. Experienced feeders in England have found that dairy cows in Winter, if fed on large quantities of roots, particularly Mangels and Carrots, will eat but little straw and become very lean; but that they will always eat a full portion of sweet, well-harvested straw, when they get a moderate allowance of roots—say 15 lbs. of mangels three times per day. Those who have roots can easily experiment in this direction,

and perhaps arrive at conclusions profitable to themselves and to the whole community. We should be pleased to record their results in the *American Agriculturist*.

Northern Sugar—Sorghum and Beets.

Many farmers may be discouraged by lack of success with the Sorghum this year, and so give it up as a farm crop. In this they will err. Corn has suffered equally by frost and drouth. It has been abundantly proved that an excellent syrup may be very economically obtained from the Chinese sugar cane, and from several of the varieties of the Imphee or African cane. It is most conveniently and cheaply produced, when the operations of expressing, concentrating, and clarifying the juice are conducted on a larger scale than most farmers would like to manage. So it has come to pass, that throughout the country, establishments have been erected, each capable of making several thousands of gallons of syrup. Many of these have this year stood comparatively idle, and the fear is that farmers will not contract to plant another season.

The production of beet sugar is now in its very infancy in this country—not a pound has ever been in the market, and yet we anticipate for it a great future. It is already demonstrated that the sugar beets will grow upon the prairies and in Ohio, standing such drouths as that of the past season, and still maturing what would be considered good crops in Europe, and very rich in sugar. This sugar we surely can extract as well as the people of France and Germany. It requires a good deal of capital, expensive apparatus, in fact a large establishment. No syrup is produced—the uncrystallizable sugar is inseparably mixed with substances of offensive flavor, and is therefore fit only for distillation. Up to the present time sugar has not been produced from the Sorghum in sufficient quantity to appear as such in market, but syrup is, and we suspect will be, the only product. These two industries, Sorghum culture and Sugar Beet culture, do not directly interfere, except so far as they both supply sweets.

The question whether cane sugar exists at all in the juice of the Sorghum is answered affirmatively by Mr. Wetherill, chemist to the Department of Agriculture. Still this gentleman after a labored discussion of the subject fails to make clear distinctions between grape-sugar and fruit-sugar. He acknowledges his own inability to prepare or procure pure grape-sugar, and fails to show the economic value of the syrup, containing as he asserts, a mixture of the two; for while the grape-sugar is not more than half so sweet as cane-sugar, the fruit-sugar is equally sweet.

Experiments conducted on a large scale to prove several questions in regard to the Sorghum are now in progress, which we anticipate will at least settle the question whether any marketable cane-sugar can be produced.

For feeding, the beet refuse forms one of the most valuable products—in fact the extraction of the sugar does not apparently reduce the value of the crop for cattle feed at all.

Talks at the Fruit Growers' Meetings.

These meetings have been interesting of late. Pears and grapes have occupied considerable attention—the different varieties, methods of cultivating, and training. The grape, particularly, is exciting much interest just now, and the question at a recent meeting was: "What Grapes shall we plant by the acre?"

Mr. Fuller said he had little hopes of the new seedlings sold at high prices. He would as yet trust only two, on

an extensive scale, viz.: the Concord and Delaware. He was very severe on parties who had sent out some of the late seedlings, which they well knew, or should know, would prove failures. This had a damaging effect on the cause by discouraging parties from trying sorts which would succeed. The Concord may safely be planted largely, for if something better is found after a few years, the Concord vines may be then dug up and thrown away, and they will have abundantly paid for themselves.

Mr. Judd endorsed the Concord, which if pitched into a man's lot would be likely to take root and grow, while the weak growing newer sorts would soon die with the care, or rather the lack of care, they would receive at the hands of most farmers.—He would have the Delaware, the Allen's Hybrid, the Creveling, and other new promising sorts pushed forward as experiments, and to supply smaller quantities of choice grapes, but for the million, he would place the Concord as one of the first.

Mr. W. S. Carpenter took the ground that we must educate the taste of growers and consumers, until the foxy sorts would not be relished by them. He thought the Concord would soon be discarded for the finer flavored Delaware, Iona, Adirondac, etc.—persons that would take no care of vines did not deserve to have grapes.

Mr. Fuller formerly had some faith in the Diana, but owing to imperfect ripening, will dig most of his up; has hopes of Creveling, but wants to see 100 vines in bearing, before endorsing it—Concords can be grown for 5c. per lb.

R. L. Williams, of Steuben Co., N. Y., had travelled pretty extensively over the grape regions of this State, and especially through the vineyards of Naples and vicinity, where there are from 50 to 100 acres of bearing vines, mostly Isabellas, with some Catawbas. They raise these sorts because the vines are cheap, are easily grown, and the grapes sell well in market, some of them unripe it is true, but they bring paying prices. The Catawba ripens better than Isabella in that vicinity, and is really a good grape; the Isabella is hard and sour. All grapes do better away from the coast; a limestone formation is best.

Mr. Fuller did not want to see a grape vine shed its leaves early, as his Adirondac did by the first of September; leaves are necessary to ripen wood and perfect fruit. If the Adirondac will only hold its leaf, it will take rank among the good grapes, though it has no very marked flavor to please any taste.

E. Williams saw some rot and mildew among his Concords, in New Jersey. Dianas were also affected—the only sorts entirely free, were Clinton and Hartford Prolific.

Wm. Clark, of Northampton, Mass., showed fine Concords grown under glass, where they had hung a month after ripening. They matured several weeks earlier than the same sort out of doors.

Dr. Ward thinks the Concord improves each year. A strong vigorous grower, it resists deleterious influences around it, to which the Isabella gradually yields.

THE PEAR claimed a large share of attention at some of the meetings. Dr. Ward showed Beurre Superfine, which he esteems as a pear of high flavor. The tree is a thrifty, vigorous grower, and bears well. It should form one of six varieties for market. He will cultivate it extensively—fruit hangs on well, even after the foliage has gone. In response to the inquiry what manure was best for the pear, Dr. Ward says he uses all kinds, and nothing comes amiss, but prefers barn-yard manure, unfertilized, applied to the surface in November—would give a tree two or three wheel-barrow loads.

Mr. Carpenter spoke of the Sheldon, as one of the very best sorts either for the amateur or for market. If he had but one sort, it should be the Sheldon, grown on the pear stock. Beurre d'Anjou was a very fine pear, worthy of more extensive culture, is a strong grower, good and early bearer. He is planting a new pear orchard, one fourth Beurre d'Anjou, one third Sheldon.

Mr. Field endorses Beurre d'Anjou and Sheldon, but were he to plant a pear orchard, he would set it wholly to dwarf Vicars, and then bud or graft in the branches, to secure strong uniform growth. If a variety of sorts be set out, the orchard soon presents a very uneven appearance.

Dr. Ward replied to the inquiry, how to plant pear trees, that he trenched, or subsoiled his ground, and then dug large holes two feet deep, filled up one foot with inverted grass sods, trampled solid, covered with loam and set the tree in this, filling in and sifting the fine earth carefully among the fibres, and spread a mixture of muck, lime, charcoal, and decayed manure over the whole.

Dr. Trimble likes the Beurre Clairgeau for its thriftiness. It seems to rejuvenate weak sorts when grafted on them.

Dr. Ward endorses its growing qualities, the grafts always bear the year they are set, when put in old trees.

Mr. Carpenter says it is too great a bearer, and the fruit should be thinned—does not do well on quince, spoke of the premature ripening of pears and other fruit, owing to the drouth in Summer and Autumn—finds fruit does not keep as well on young as old trees.

Dr. Ward had observed the same thing. He had already (Oct. 26,) picked his Winter pears, including Lawrence, which he usually left on the trees much later.

A Country Dwelling of Medium Size.

So much of the comfort of life depends upon the arrangement and conveniences of one's dwelling, that we purpose devoting a little more attention to this department of the *Agriculturist*, now that we have more editorial aid. A different arrangement of rooms, closets, etc., may make a vast difference in the convenience and utility of two dwellings erected at the same cost.

Perhaps the best way to draw out information is to solicit plans, hints, and suggestions, from our readers. We present herewith the essential portions of a very neat colored sketch of his own dwelling, furnished us by "Jack Plane," of Burlington, Iowa. This house he has occupied a year, and says he has no fault to find with it. (It is almost exactly like a village dwelling we boarded at, when at school many years ago, so we are pretty well acquainted with it.) The engraved plans show at a glance, the general internal arrangement, and the figures give the dimensions of the rooms. The cellar is under the whole house, as it should always be, and is 6½ feet

high in the clear (which is too low for convenience). The first story is 9 feet in the clear, and the second story 8 feet. The rear part is 9 inches lower than the front or main building, to let the roof come clear of the chamber windows. A second cellar stairs leads from the dining room, under the hall stairs. Cost about \$1500

REMARKS.—While the general plan seems to be a good one, there are some defects that might perhaps be remedied by a different arrangement. The dining room is of course used as the general living room, and the 'living room' kept more

choice, especially if there are children to mar the furniture. There is not enough closet or pantry room on the first floor. This point we consider an essential one in every dwelling. There are a hundred articles in every family that come into almost daily use, and labor, steps, and time should be saved by having closet and shelf room for all such articles on the living floor. Books and papers may be kept in furniture cases standing in the main rooms, and the better hats and overcoats may be placed on a rack behind the hall door, if there be room; but we would always recommend a spacious closet in or adjoining every living room, where common overcoats, cloaks, hats, etc., may be kept conveniently at hand—otherwise the chairs, table, or mantel-shelf will be constantly called into requisition.—The main closet in this plan can only be reached by going through the bedroom, where perchance a sick person may be disturbed.—The bathroom is so located as to be inaccessible to persons in the chamber,

without passing through the whole house, including the kitchen, and also through the open porch. Should not the sink be on the

Fig. 3.—PLAN OF FIRST STORY.

sink, must be carried from the dining room through two doors, and then back through three to get them into the china closet! These are

Fig. 4.—PLAN OF SECOND STORY.

minor items, but everything that saves steps saves time and labor. Dishes are to be used 1095 times a year.—There is hardly closet room enough in the second story. One or two dresses of modern style will fill a small closet, and can hardly be put into a wardrobe standing in a room. Perhaps the 6x7 room over the hall may answer for general storage. If this room be used as a bedroom it would often be convenient to have it connected with the front chamber by a door. There is, however, one closet not shown, under the attic stairs. This may be extended 9 or 10 feet, or more, and if needed take one foot from the other room to be added to this one. These remarks are merely offered as general hints to help others in planning. We shall give other plans and hints from time to time.

Query About Prairie Dwellings.

In traveling thousands of miles through the West, during the past season, we could but notice that nearly all the dwellings are constructed a scant story and a half high, the first story 8 to 9 feet high, and the second only 3 to 5 feet at the eaves. Now it requires just as much cellar, flooring, roofing, framing, etc., for such a house, as for a full two-story one, having high convenient rooms above, with attic room also. The only difference in the cost is for a strip of 3 feet all around, requiring merely a little longer posts, a few more boards for siding, and a slight outlay for lath and plaster. We should say that for the ordinary prairie houses, costing \$700 to \$1200, forty to sixty dollars more would be all the extra cost of a convenient two-story house, over one having the same ground space, but only 1½ or 1¼ stories high. A little figuring will show that a house 20 feet square, and 17 feet high has the same amount of walls, as one 22 feet square, and only 14½ feet high, while the former has 168 square feet less of flooring, and of course costs less. Query.—Suppose the extra \$40 to \$60 cost can not be added to the 22 feet square house, to run it up 2½ feet higher, would not a full two story house 20 feet square, be preferable to one 22 feet square, and only 1½ stories high?—We know there is one argument in favor of low houses on the wind-swept prairies, but a few extra braces would make up the extra strain of two or three feet more in height.

right hand of the pantry, next the bath-room, instead of on the left, or rather should it not be in the kitchen? The dishes, if washed in the

Nepaul Barley—Large Results.

Three years ago last Spring, Mr. Isaac Watkins, of Orange Co., N. Y., received from the office of the *American Agriculturist* one of the little seed parcels distributed among subscribers, which contained a sample of the Nepaul Barley. This he planted in the garden in a 3x4 feet bed. It yielded $3\frac{1}{2}$ quarts, which was sown broadcast in the field the next Spring, but the cattle destroyed a part, so that he only got about $\frac{1}{2}$ bushel. Last year the $\frac{1}{2}$ bushel yielded 9 bushels, weighing 71 lbs. per bushel. His neighbors were so desirous of getting it, at \$5 per bushel, that he let five bushels go for \$25. The remaining four bushels he sowed this year on about an acre, and it yielded a little over 40 bushels. Mr. W. thinks it will produce fully a quarter more per acre than the common variety. (Mr. Watkins says, this is only one of several ways in which he has been more than repaid for his investment in a subscription to the *American Agriculturist*.)

Ice-Houses.

The views of both practical and theoretical men have changed much, within a few years, about the preservation of ice. Why ice keeps ordinarily better above ground than below, is explained in sundry ways: the fact is acknowledged. Why ventilation is necessary to the successful keeping of ice in small quantities has been likewise the subject of many learned explanations which, however, do not well agree. Still it is a fact. In keeping large quantities of ice, it is only necessary to pack it in a compact mass in a building which will shield it from the direct influence of the rains and sunshine, filling in straw or sawdust between the ice and the walls, or having the building double walled, and the space between the walls filled with tanbark, sawdust, or similar porous and non-conducting material. The ice-house should be constructed so that it may be easily filled, and the ice easily gotten out, bearing in mind that a mass of ice melts only on its surface, if well packed. It is desirable to have a double roof; absolutely necessary to have perfect drainage; desirable to prevent draughts of air coming up through drains, or striking the ice anywhere, and absolutely necessary to have ventilation above the ice—that is, above the straw or sawdust which covers it. This ventilation ought not to be a draught of wind, but only enough to keep the air from becoming close and damp.

Farm or family ice-houses must be constructed on the same principles, but the amount of surface exposed being so much greater in proportion, it is much harder always to secure the conditions necessary to keep the ice with little loss from melting. We advise no one to build an ice-house that may not contain a mass of ice 10 feet square, and at least 8 feet high. 12x12 by 10 feet high is a good size. For convenience in filling, the house may be set on a side hill. It is well to sink the bottom a little below the surface of the ground after leveling, to cement the bottom, and to provide drainage secure from currents of air passing through the drain. Eight inches is sufficient space between the outer and inner boarding, and this may be filled with any non-conducting material—spent tanbark is perhaps as good as anything. The building should, we think, be entirely of wood, not even having the side toward the hill of stone wall. The door for filling, which must be

in the gable, toward the hill, may serve also for taking out the ice, and ordinarily, it is best it should. A sliding pannel in this door, opening a hole a foot square, will furnish ventilation and the means of regulating it. The roof should be well shingled with extending eaves, and the rafters boarded over to prevent the too great heating of the air above the ice.

Willow Fences and Wind-Breaks—Report of Personal Observations in the Field.

During two years past there has been no little excitement in regard to the practicability of using the White Willow (*Salix alba*) for fences, especially upon the vast prairie regions of the West where fence-timber is almost inaccessible. The Osage Orange is successful south of latitude about 40° in Illinois, but is not always reliable north of this line, and there is a great need of a plant to fill its place. While in Illinois last season we tried to collect some items, but were not very successful. Having gathered some rather striking facts in regard to the willow in central New-Jersey, we deemed the matter of sufficient importance to send one of our associates of good judgment (Mr. Weld) to Illinois to make a thorough personal examination of the whole subject. Mr. Weld started Oct. 20th and was absent nearly three weeks, visiting Ogle county, where the willow has been most thoroughly tried, and extending his journey to some other parts of the State, to examine the Osage Orange hedges, and other matters of interest to our readers, of which some account will be given in future numbers. He visited several farms where the willows have been tested for fences, and for wind breaks, from two to twelve years, and reports as follows:

My visit to Ogle county, Ill., was in company with gentlemen intimately familiar with the agriculture of the prairies, with the soils and seasons, the crops and modes of culture. We traveled many miles, and examined a large number of localities where the willow fences are in use. We found a few hundred yards of fence 11 years old, the first planted in this county, or State, some also on the same farm, set during the immediately subsequent years—but of fences planted within the past 4 or 5 years, particularly that 1, 2, and 3 years old, we saw miles upon miles, throughout this entire region. Thus the conviction comes to my own mind, that where it is best known the willow is most highly esteemed. We observed poplars and cotton wood, and poor powdery locusts, and the yellow willow too, all giving way to the white willow. The 11-year-old trees were planted at first merely as a wind-break; cuttings of finger size and a foot or more in length being stuck in the prairie sods, a foot apart, so says the planter. From many cuttings two or more shoots starting from the ground must have been allowed to grow, for as the trees now stand, 10 to 12 trees occupy about 8 feet length in the row.

The cut illustrates the manner in which the trees occupy the ground, but they are larger and more completely fill the row than the cut represents. Lack of time and space prevents giving in this number a picturesque view of the fence. The trees now stand at least 40 feet high. The trunks at a height of 2 or 3 feet are from 6 inches to a foot or more in diameter, and rise with a uniform taper, and very straight,

to the top. They incline a little, uniformly, showing the effect of the prevailing winds, but not one, that we noticed, was broken or had lost an important branch, nor had one died. There is one vacant space of a few feet where a pair of bars had been. The land on which this row of willows stands is good corn ground. On the east side it has been for several years in cultivation, and now sustains a luxuriant growth of clover and timothy. The land on the exposed side of the fence has never been plowed, and is prairie grass, tamed by the grazing of cattle. In this, numerous roots extend near the surface to a distance of a rod at least, as I proved by digging, and doubtless they go further in some cases. These roots, however, were not so strong as to prevent plowing within say 16 feet of the fence. On the cultivated side, at eight feet off, no roots were found of large size. Still nearer, where the plow had been run closest to the trees, matted fibres abounded, and some as large as one's finger were stretching out into the field. The grass grew well within 6 feet. The owner of the land estimates that as a wind-break, the influence of this screen is felt for several hundred paces, making the land earlier and more productive, preventing the lodging of grain, the blowing down of corn, etc.

In a few places the trunks spread apart at a height of a few feet above the ground, so that a man can easily get through, but no farm stock could do it, and a better stockade would not be needed to confine a herd of elephants. To make it dog-proof, would require only a little labor and a few stakes.

The appearance of the fence is attractive, the height of the trees being very uniform; and even when the fences extend over dry knolls and through "slines," (sloughs,) the result only is to make the line of the tops a little less undulating than the ground line, showing that the willows grow faster in wet soil than in dry.

On the same farm there were some yellow willows, set at the same time, as we were informed. They had not made nearly so good growth, and there were numerous vacant spots where trees had died. They were more branching and crooked also. One farm which we visited was not only fenced externally, but the owner was dividing up the land into 10 to 15 acre lots, using the willow exclusively. Much was set on this farm last Spring. It was well cared for, and the growth, though small, was healthy. Here we saw no dead cuttings. There was also about an acre set last Spring for timber, fuel, etc., the cuttings being a foot apart in rows 12 feet apart. The ground has been regularly worked all Summer, and the plants look well, having made a growth of two and a half to three feet. Some of the older fences on this farm were originally set too loose, and the result is that in the four-year-old hedges spots are not infrequent where an animal might work through. It had been attempted to remedy this by setting some large cuttings to fill the gaps. They had all failed. The willow cutting must have light and air; it will not grow in the shade of either weeds or older willows.

From what I have seen, and from the views of those who know most about the White Willow, I am of opinion: 1st. That it will grow on all good soil, and in wet soil; 2d. That in four years, it will make a fence that will turn all domestic animals, if it be topped at a height of four feet, and the tops used to strengthen the hedge somewhat; 3d. That left to grow it will in 5 years, or 6 at most, make a fence without topping, so that this fence will be an effectual

wind-break, and after it is 9 or 10 years old, and periodically thereafter, will furnish a large amount of good firewood or durable fence-rails; 5th. That if the plow be run once every year or two at a distance of a few feet from the fences, the roots will not interfere materially with the culture or products of the soil; 6th. That the roots will not send up sprouts either before or after the removal of the tree or stump.

In regard to planting and subsequent care, I consider it indispensable to plow several deep furrows each side of where the cuttings are to be set, to remove all weeds and grass, to let but two or three stems grow upon each plant, to keep the ground open and well tilled the first year, and to see that cattle do not browse it. There is no doubt of the fact that animals will eat it, though we saw no hedges especially protected from cattle, nor damage done by them, nor did we hear complaint in this respect, but this ought to make no one less careful to prevent damage to his young fences from such cause.

While I do not say that, of the many quick-growing trees and hedge plants, which are used for timber-belts, shelter-belts, wind-brakes, fences, etc., on the prairies, the white willow is certainly best for each of the purposes of fence, wind-break, firewood, and timber, I now believe that it will be found to combine them better than any other yet brought before the public. Where the willow is known, and among those who have visited that part of the country where the fences may be seen, I have not been able to find a man who did not regard its claims to the favorable consideration of prairie farmers at least well founded.

There were many miles of cuttings set at the West last Spring; we saw some of these which had started well, but had died during the drouth, and heard of many more such. In my own opinion the failure of many cuttings last season militates no more against the use of the willow on the prairies, than the almost total failure of a corn crop does against its continued use. The drouth was extreme; corn, sorghum, tobacco, and grass, were much affected, and the early frost destroyed much of what had withstood the drouth. M. C. WELD.

Breaking Up Prairie Land.

Several have written in response to an inquiry on this subject in the *American Agriculturist*, and most of them agree on the main points. We give here two communications which include the more important particulars, and coincide with the opinions we have heard expressed with great uniformity by prairie farmers, during our trips West.—Mr. John E. Darby, Muscatine Co., Iowa, writes: "The first point of importance is the season of the year for breaking. This may vary slightly in different years, but as a general rule, the very best is the month of June. The operation may be commenced as soon as the young grass is sufficiently started for pasturage, and be continued until harvest. This gives a range of time from the middle of May until the middle of July. If done earlier, weeds sprout up through the sod; the grass also comes up and renders it tough to work the next year. If later, the sod does not rot sufficiently for wheat, though it generally lies clean and brings good corn. I can see no difference in the rotting, whether left smooth or rough, but it is far pleasanter working smooth, and a plough laying a smooth furrow runs lighter. New sod is good for almost any field crop, and gives the surest chance for spring

wheat, which is never or rarely injured by chinch-bug or rust, and less liable to smut. Wheat is sown on the sod as soon as possible in the Spring, always without stirring, but thoroughly harrowing, which is easily done if the sod has been properly broken, and at the right time. For corn, the sod must be re-plowed in the Spring. This is easily done, if the sod is well rotted, and it generally will be if broken in June; but if the sod is a little tough or raw, a rolling cutter is of great use. Plow an inch or two deeper than the breaking, and proceed as on sward in the East. Another thing of importance is, to break as shallow as possible; 2½ to 3 inches is sufficient, the sod rolling better than when broken deep. In "roughs" or bushy land, it must necessarily be broken deeper.

"Another point is, to have the land freshly burned, if possible: mark it off, burn the old grass, and break immediately. If the grass gets too high, the sod does not rot so well.

"A word as to mode. Breaking prairie was formerly almost exclusively done with ox-teams, from 3 to 6 yokes to a plow, the plow cutting from 18 to 28 inches. This made it necessary to employ regular "breakers," as not every one could afford to keep such a team; but now, smooth prairie is frequently broken with two or three good horses—if three, worked abreast. A plow of 10 to 12 inches cut, and of sharp wedge-like form, is used, and some prefer this kind of breaking. I have done considerable in this way, and with two medium horses can break from 1 to 2 acres per day. A poor man can thus make a farm with little expense beyond his own labor."

Mr. John W. Barrett, Pierce Co., Wis., writes: "The best time, or I might say the only time to break up prairie land, is from the 1st day of June to the 20th of July. The reason is, that broken before June, the grass does not get a good start, and it will turn and grow through the breaking. If it is done in June and July, the grass has a start, and when broken with a hot sun on it, is sure to rot. Have the sod all turned over, and let it be as rough as possible to make it, as when in this condition, it is more easily torn up and prepared for seed harrowing in the Spring. Wheat is preferable for the first crop, and also for the second. My own practice is to break my land in June, then sow turnips or ruta бага seed, which usually pays for the breaking. The following Spring I use a large cultivator, dragging it over twice, then sow wheat and drag twice again, which is sufficient, if the land is broken at the right time. The sod rots better when rough than when laid smooth and even."

"Why will not 'wild' prairie sod rot like that of 'tame' grasses at the West and East?" is a question we repeatedly asked, and received the response that the roots of wild grasses and weeds are so tenacious of life that they can not be effectually killed, and the sods made to decay, if turned under deep. In opposition to this view we have a single fact to present, and our prairie readers may draw their own conclusions. Mr. Theodore Gennert, of Livingston County, Ill., (the same of whom mention was made in the September number of the *American Agriculturist*, (page 270,) as testing on so extensive a scale the question whether sugar may profitably be made from the beet, in this country,) plowed the land for his beets, and for a considerable corn-field, to the depth of 10 or 12 inches, the latter being reached whenever practicable. Double Michigan plows were used, and the top paring of sod was covered

with 9 inches of mold. Mr. G.'s beets were the only good field crop we saw in Northern Illinois in October, and his corn, though "sod corn," and somewhat damaged by the frost, was by far better than any corn raised on old land which we saw, in that region. It stood the drouth well, and a large portion of the crop was so far matured as to be uninjured by the frosts of August and September. "Sod corn"—that is, corn planted immediately upon the sod—is seldom worth harvesting, as we understand it, except by cattle and hogs, and this year we saw none which appeared to have paid for planting.

To Prevent the Flavor of Turnips in Milk.

D. McM., of Ulster Co., N. Y., writes to the *Agriculturist* that he has fed turnips to cows for over 30 years and has never been troubled by any unpleasant taste in the milk. He cuts the turnips by means of a root cutter and spreads the pieces in a layer two or three inches thick, upon the floor of the barn or other convenient place, where they remain for 24 hours before they are fed out. He considers that by this exposure the flavoring principle is dissipated, and the turnips may be fed without risk of imparting much taste to the milk. This is certainly a very simple plan and is much to be preferred to the use of saltpetre, and other drugs of doubtful efficacy, which have been recommended as a preventive. A gentleman who has had much experience, informs us that he never found any bad taste in the milk, if the turnips were fed after the morning milking, but that it was always bad flavored if they were fed at night.

How Farm Laborers Live in England.

The *Agricultural Gazette* (England) reports upon the condition of the agricultural laborers in Norfolk County. Two closely printed columns are filled with statements like these:

"A man, his wife, and seven children occupy a small place not large enough to be called a room, being, in fact, the place between the ceiling and the roof. Here we find the man, his wife, a daughter aged 20 years; girl, 16; boy, 13; girl, 11; boy, 8; a girl, 6; and a girl, 3; the only ventilation and light are by one square of glass 11 in. by 9 in."

"A dilapidated old cottage unfit for human habitation, neither wind nor water tight; two bedrooms, one occupied by a man and his housekeeper, and the other by his five children. The windows are stuffed with rags, and the floor full of large holes, with large cracks in the walls. The lower floor is pulled up; pieces of wood stretched across the rooms to support the roof; a disgraceful place used as a privy, without any door, and drainage run into an open ditch."

Let our farm laborers read the above, and be thankful that it is different with them. No wonder that laborers are ready to leave a country, the social system of which subjects the tillers of the soil to such degradation. In the same paper we find it stated that a similar condition of things exists in Hampshire.

SALT CATTLE REGULARLY AND UNIFORMLY.

—A correspondent thinks he has traced several cases of cows slinking their calves to their hay-ing eaten inordinately of salt. Either salt cattle regularly and uniformly in the manger, or let a lump of hard rock salt be accessible at all times, which is the better plan.

AN ABSURDITY.—A young man complimenting his sweetheart by telling her that her breath has the sweetness of roses, without shame that his own has the stench of whiskey and tobacco.

To Eradicate Sorrel.

Lime is often recommended to kill out sorrel; the alleged reason being, that the oxalic acid in the sorrel shows that the soil is sour, and to remedy this we must apply an alkali, like lime. Doubtless, good often comes from such application of lime, but not for the reason here given.

The presence of oxalic acid in sorrel is no better proof that the land is sour, than is the acidity of an apple or of the rhubarb plant. The same ground which grows a sour apple, will grow a sweet one: the two often grow on the same tree. The vegetable acids (of which oxalic is one,) are produced in the organism of the tree or plant, and not in the land. True, the elements of the acid are gathered from the soil and air, but they do not exist in the acid form which we find in the plants. These very elements when taken up by a potato plant form starch, when taken up by a corn plant form sugar, and when taken up by a grape vine form tartaric acid. If the soil itself be as closely examined as science will permit, there will be found neither the starch of the potato, the sugar of the corn, the cream of tartar of grapes, nor the oxalic acid of sorrel. In view of these facts, then it is useless to apply an alkali to the soil to neutralize an acid which does not exist there.

But is there, then, no way of eradicating sorrel? Yes. It spreads, like quack-grass and Canada thistles, chiefly by under-ground stems, with numerous joints, each of which will form a plant. Break up the land in July and August, and put in a crop of buckwheat or rutabagas, and the intruder will be pretty well snubbed out. So, a corn crop or other hoed crop, if well tilled in mid-summer, will answer a good purpose.

Dressings of the soil are also very important. Applications of lime are useful to decompose vegetable matter, and so to "warm up" the land, and quicken the growth of plants. Chief of all in value, is barn-yard manure, applied copiously, and well worked in. This gives strong food for the vigorous growth of other plants than sorrel, and when they occupy the land, this badge of an impoverished soil will disappear.

A New Potato Grown without Vines.

In the basket columns of the November *Agriculturist* will be found an account of the manner in which new potatoes are sometimes produced without vines. A friend has brought us a remarkable illustration of this. A potato was accidentally buried under a brick pavement, where it was warm enough to induce growth, but under conditions where branches could not reach the light and air. The engraving represents the appearance of the potato, the old tuber being completely shrivelled and exhausted of its substance, while the new one is fresh and plump. Had this old potato been planted in the field, the nutriment contained in it would have gone to produce stems and leaves, but in this case, as there was no chance for these, it was consumed in producing an underground stem or tuber. There was simply a transfer of the

starch and other matters contained in the old potato, to the new one. This growth went on with such force as to lift a brick in the pavement, and thus led to its detection; this will account for the flattened shape of the potato.

An Improved Horse Stable.

A letter on Horse Breeding, addressed to John E. Dennison by W. Dickenson, read before the Royal Agricultural Society of England, describes the stables for *Draught Horses*, used by the writer. The engraving of the plan given above will make the following description clear.

"The stable should not be less than 18 feet wide, and of such a length as will allow 6-feet standing for each horse. It should be 10 feet high. The horses stand in a single row, and the harness is hung on pegs in the wall behind them. This width admits of thorough ventilation to the stable, without subjecting the horses to draughts. Each standing should be parted off by an upright post reaching from the ground to the ceiling rafter, placed 3 feet from the wall at the horse's head. These partitions should be closely boarded up 3 feet above the manger and hay crib, to prevent the horses quarrelling about the food, and biting each other. To each of these posts a "bale," 8 feet long and 20 inches wide, should be hung by a strong chain, to divide the standings, and suspended by another strong chain at the hinder end from the ceiling rafter. Each chain should have a hook and eye within reach, that may be readily unfastened. This arrangement will leave a space of 6 feet opposite the head of each horse, available for feeding purposes. The manger for corn and chaff (cut feed) may be 2½ feet long. It should be 2 feet wide at the top, 1 foot 2 inches at the bottom. The hay and straw, which should be cut into 6-inch lengths, will require a larger receptacle, which should be 3 feet 6 inches long, 2 feet wide at its upper part, and half that width below. It should be so constructed, that while it is even with the manger above, it should reach to the ground, 2 feet above which should be fixed to the wall a bottom, sloping to 1 foot above the ground in the front, where some upright openings should be cut, to allow the escape of the seeds and dirt.

At the top of this hay and straw crib, an iron rack with bars 6 inches apart, should be so hung as to open up and fall back against the wall to let the fodder be put in, and then be put down upon it for the horse to eat through. It should be so much smaller than the opening that it can fall down with the fodder as it is consumed, by which means not a particle is wasted. The manger may be constructed of yellow deal 1½ inches thick for the front, back, and ends; the bottom, of slate three-quarters of an inch thick.

The top of the front and ends should be covered with half round iron, 2½ inches wide, screwed on to project over the front, a quarter of an inch outside, and three quarters of an inch inside the manger. This prevents the food being tossed out, and the manger being gnawed. A short post

must be put up as near the centre of the standing as possible, to support the manger, into which a large screw ring must be put to let the chain or rope of the headstall pass freely up and down without constant friction. The manger may be 3½ feet from ground to top; the hay-crib of course the same height. The paving of the standings, to 3½ feet from the head should be flat, then with a fall from both sides to the centre, where an angle iron drain of 4 inches wide from end

to end, with a removable flat iron cover fitted to the inside of it, should be placed straight down the standing, with a fall into another larger cross main drain 10 feet 6 inches from the head, so placed as to carry away the urine from all the smaller drains into a tank outside the stable. This main drain so placed, takes the urine from the mares, and has a loose cover also fitted to it, easily removed for sweeping out when necessary, perhaps once a week. This system keeps the stable healthy, economizes the urine, and the straw also—the latter very important where it can be sold, or consumed as food. The width of 18 feet for the stable gives room for narrow corn bins 3 feet high, so that each carter may have his horses' corn separate."

The writer proceeds to describe his method of ventilating, which we omit because we have repeatedly published superior ways, which are of universal application. In some respects the stable described may be considered needlessly expensive, but when one builds a stable to last 100 years and to need no repairs, some extra expense at the outset is a good investment.

A New Remedy for Moles.

An article in the *Horticulturist*, recommends castor oil pomace to drive away moles. It says: "We have not tried it sufficiently to give it a thorough test, but we have the most implicit confidence in the assurance of a friend, who says that he has used it for many years with uniform success, driving the moles entirely from his place. The run of the mole is to be opened, and some of the pomace placed in it. The pomace has a very offensive smell, and is supposed to act by diffusing its strong odor through the run. It should not be placed too near plants, as it is very acrid, and will destroy them." Perhaps this is worth trying, as we know that castor oil beans have been recommended by many persons, who say they have used them with success. The pomace may be had of Mr. Lane and other dealers in fertilizers.

"BAD FOR THE COW."—When Geo. Stephenson was presenting the claims of his first Locomotive to the British Parliament, he was sneered at by many members. Said one of them: "Well Mr. Stephenson, see how absurd your idea is. Suppose it were possible for you to run your carriage twenty miles an hour, on straight rails so that it could not get off. What if a cow

got on the track, and you could not turnout for her?"—"Well, my Lords," said Stephenson, "*It would be bad for the cow!*"

A Talk Over a Cabbage.

The cabbage is so common an article of food that it may be supposed little can be said about it, not already sufficiently well known. Perhaps we may be able to show that its real nature is not generally understood. What is the cabbage? In the beet, carrot, and parsnip, we eat the root; in the potato, the underground stem; in asparagus, a tender above ground stem; while in spinach, it is the developed leaves which furnish food. What is the eatable portion in the cabbage? We answer, a large *bud*. A little study of the cabbage and comparison with other plants, will show that this is so. Let us compare it with a twig of one of our hardy trees—the horse-chestnut will answer best because its buds are large—and see if there is not a great similarity. Upon a twig of horse-chestnut (Fig. 1,) we have a large bud at the end, the *terminal bud*, and smaller ones along the sides of the stem. These smaller buds grow just above the scars left by the fallen leaves, and before the leaves fall, they are found in the

Fig. 1.—HORSE CHESTNUT.

axil or angle made by the union of the leaf with the stem. On account of their position these buds are called *axillary*. The figure shows the stem with its terminal bud, and the axillary buds separated from one another by a considerable length of stem. These buds contain the rudiments of the next year's growth, as we shall see if we cut one of them open. Fig. 2 represents a diagram of a section of the terminal bud of the horse chestnut. It is found to be filled with leaves packed in and folded one over another, and all upon a stem, the joints of which are so short that the lower part of the leaves touch one another. The whole growth of the next year is here, in an undeveloped state. When vegetation starts in Spring, the short stem in the bud will elongate, and the leaves will expand to their full size, and thus complete the growth which has been prepared for and commenced the year beforehand. In most of our hardy trees and shrubs the annual growth is made in a very short time, and the rest of the season is employed by them in ripening the wood and in preparing more buds for the following year. A terminal bud is again formed, the growth of which will lengthen the stem, and others are formed in the axils of the leaves which will develop as side branches. With this brief sketch of the growth of a woody branch, let us see what there is like it in the cabbage. The early growth of a cabbage is much like that of a woody twig. The first leaves are at some distance apart, and as the lower ones fall away, after they have contributed to the growth of the stem, we find that they leave leaf scars (fig. 3, *a, a*) similar to those on the horse-chestnut, only longer and nearer together, and that above them are axillary buds, *b, b*. When the plant

Fig. 2.—INTERIOR OF BUD.

has obtained sufficient size and strength, it commences to form a large terminal bud, or head as we call it, and this consists, like the bud of the horse-chestnut, of undeveloped leaves crowded upon a stem, the inner leaves being gradually smaller and less developed than the outer. The figure shows the head cut open, and it is seen to be only a highly developed terminal bud, much like that of the horse-chestnut, only larger, containing numerous leaves, and in their axils quite conspicuous buds, *c, c*. In this condition the cabbage passes the Winter; when it is planted out in the Spring, the buds in the head start, and being supplied with the abundant nutriment which the fleshy stem and the thickened leaves

Fig. 3.—INTERIOR OF A CABBAGE.

contain, they grow very rapidly and bear flowers and seeds. If the head be removed and the stem or stump alone planted out, as is frequently done, the axillary buds, *b, b*, will start and throw out vigorous shoots. By cultivation and selection, varieties of cabbage have been obtained in which the terminal bud attains an enormous size, while in its natural or wild state this is very small. To keep up the peculiarities of the different varieties, the best cultivators raise seed from well developed specimens only, the whole cabbage being planted out and only a few of the central shoots allowed to grow. In this way the whole vigor of the plant and all the accumulated nourishment is thrown into a few stems. Sometimes cultivators are much troubled with the bursting of the heads, especially with the early varieties. This usually takes place when a rain succeeds a drouth. The outer leaves stop increasing in size in a dry time, and when a succeeding rain causes the interior of the head to increase, the outer leaves do not grow, and being closely wrapped over one another, can not yield, but are ruptured by the pressure from within. We know of no other remedy than to lift the plants and thus stop their growth. The late sorts are not apt to be affected in this way.

LONG MILES.—Prentiss says: "Recreants to their country's service should be scourged wherever they go. Upon the road they travel there should be more than three hundred and twenty rods to every mile."

Fattening Sheep in Winter.

If properly managed, the winter fattening of sheep may be made profitable. The first point of importance is, to have them come in from the pasture in thriving condition. It will hardly pay to attempt to winter poor weaklings, especially where large numbers are kept; better secure their pelts at once; fattening such animals at this season is out of the question. The following letter from John Johnston, Esq., of Geneva, New-York, wellknown as one of our most successful farmers, is to the point—we extract from H. S. Randall's new and valuable work on sheep: He says: "I generally buy my sheep in October. Then I have good pasture to put them on, and they gain a good deal before Winter sets in. I have generally had to put them in the yards about the first of December. For 23 years I have fed straw the first two or two and a half months, with a pound of oil cake, meal, or grain to each sheep. When I commence feeding hay, if it is good, early cut clover, I generally reduce the quantity of meal or grain one-half; but that depends on the condition of the sheep. If they are not pretty fat, I continue the full feed of meal or grain with their clover, and on both they fatten wonderfully fast. This year (1862-3) I fed buckwheat, a pound to each per day, half in the morning and half at 4 o'clock P. M., with wheat and barley straw. I found the sheep gained a little over a pound each per week. It never was profitable for me to commence fattening lean sheep, or very fat ones. Sheep should be tolerably fair mutton when yarded. I keep their yards and sheds thoroughly littered with straw.

"Last year I only fed straw one month. The sheep were fed a pound of buckwheat each. From the 20th of October to the 1st of March, they gained nearly 1½ pounds each per week. They were full-blood Merinos—but not those with the large *cravats* around their necks. I have fed sheep for the eastern markets for more than 30 years, and I always made a profit on them except in 1841-2. I then fed at a loss. It was a tight squeeze in 1860-1 to get their dung for profit. Some years I have made largely. I did so this year (1862-3,) and if I had held on two weeks longer I should have made much more. Taking all together, it has been a good business for me."

American Wool Manufacture.

The American Stock Journal gives the following statistics of wool manufactories in the United States: "In Maine there are 32 woolen factories running 32 sets of cards; in New-Hampshire 56, with 228 sets of cards; in Vermont, the same number of factories, with 122 sets of cards; in Massachusetts 154 factories, running 999 sets of cards; in Connecticut 93 factories, with 409 sets of cards; in Rhode-Island, 56 factories and 225 sets of cards; in New-York, 208 factories, with 441 sets of cards. They are devoted to the manufacture of satinets, cassimeres, cotton warp cloths, stocking yarn, worsted and woolen yarn, blankets and flannels, delaines, carpets, cashmeres, shawls, feltings, negro cloths and jeans, linseys, and a few other varieties of goods. A report on this subject was presented to the Boston Board of Trade, last year, by Mr. Geo. W. Bond, who stated that in the other States there were about five hundred sets of cards in operation. None of the finest broadcloths are yet made in the United States. Long wool with a silky luster is preferred, especially for the fabrics used for ladies' dresses."

Looking into the Birds' Stomachs.

The English papers have been for some time engaged in a discussion upon the value of birds to the farmer and gardener. Some writers contend for the destruction of the birds to save the grain and fruits from their attacks; while others warmly advocate their preservation on account of their usefulness in destroying insects, and consider that the injury they do to various crops, is more than counterbalanced by their destruction of the insect enemies to vegetation. As the *Agriculturist* has frequently advocated the preservation of the birds, we were pleased to see a list of the contents of the stomachs of birds, which were exhibited at the International Exhibition in London. The list comprises 20 of the common birds of Europe, and shows that the majority of them feed largely on animal food. Even the mischievous blackbirds are insect eaters during a greater part of the year. The stomach of the blackbird contained in *January* and *February*, seeds, spiders, chrysalids; *March*, worms, grubs, buds of trees; *April*, insects, worms, grubs; *May*, the same, and cock-chafers; *June*, the same, and fruit; *July, August, September*, all sorts of worms, and fruit; *October*, grubs of butterflies, worms; *November, December*, seeds and chrysalids. We believe that similar examinations have been made in this country and show like results, but we have not them at hand. Not only do the old birds eat great numbers of insects, but the quantity fed to their young is enormous. A gentleman who carefully watched a nest of thrushes, found that the old ones fed their brood no less than 206 times daily. Considering the great service the birds perform in lessening the number of destructive insects, we can well afford them a dessert of fruit. This view will be objected to by some who will declare that the birds cause them a great loss of fruit and grain, and there is much to be said on both sides. It seems to be a choice of evils, and the mischief done by the birds seems to us the lesser of the two. We know that in those places where birds are left unmolested and are encouraged to stay, there are no complaints of devastation by insects.

Last May we put up in trees and elsewhere a dozen small boxes with a single hole each, and they were all quickly occupied by wrens' nests. These birds destroy an immense number of insects. Next March and April we intend to put out from fifty to a hundred boxes of different sizes, and with apertures suitable for the different kinds of birds.

Sweet Potatoes Successful at the North.

A correspondent in Connecticut who made a single trial of Sweet Potatoes and failed, thinks the *Agriculturist* should not recommend their culture, in any localities north of New Jersey. It is hardly fair to form a positive opinion upon any plant from one year's failure or success. This is especially true of so tender a plant as the Sweet Potato. At our first trial, years ago, it happened to be a very wet season, and the plants ran all to vines, and made but few roots, and we did not get enough to pay the cost of the plants. Not discouraged with one season's failure, they were tried the next year, and every year since, to our great satisfaction. There are letters before us from Brown Co., Wis., Watertown, Ct., and near Providence, R. I., all speaking of great success with sweet potatoes this year. We visited the garden of J. C. Thompson, Esq., at Staten Island, at the time his po-

tatoes were dug. The crop was grown according to the method described by Mr. T., in the *Agriculturist* for April. One portion of the planting was upon ground occupied by the same crop last year, while the other was upon land which had formerly grown cabbages. Mr. T. has sweet potatoes in two different places where cabbages had been raised last year, and the yield in both instances was very inferior. Judging from this single experiment, it would appear that this crop can not properly follow cabbages. Upon the land which had borne sweet potatoes the year before, the crop was very fine, yielding at the rate of at least 300 bushels to the acre. The roots were of good size for the table, with very few so small as to be worthless. We have not the statistics relative to the cost per bushel. In addition to the above, our own experience on Long Island may be given. We set out 200 plants last Spring and have used the potatoes from the time they became large enough to cook, and are convinced that we have had a supply of better quality, and much cheaper than we could have procured them in the market, aside from the satisfaction of eating the product of our own land. They cost less per bushel than the common potatoes. We commenced early in September to examine the hills, by thrusting in the finger, and when a large tuber was found, it was taken out and used, and the smaller ones were left to increase in size, until the hard frosts late in Oct. W. H. Lewis of Ct., writes that he obtained the best results from deeply worked soil, contrary to the experience of Mr. Thompson. M. S. Shaler writes that he raised potatoes in the cold climate of Wisconsin, measuring 10 inches long and 3 inches in diameter. In answer to queries in the letters above alluded to, we would add that the vines should be moved occasionally to prevent their rooting, and that the crop should be dug as soon as the tops are touched by frost.—Next Spring we will give further directions for culture at the North. Our present method is uniformly successful.

For the American Agriculturist.

Goodrich's Seedling Potatoes.

These potatoes originated with Chauncey Goodrich, of Utica, N. Y., and have been before the public several years. They have been quite widely distributed, so that they are not a monopoly in the hands of any seedsmen, and generally sell for the same price as other good seed potatoes. I received four varieties from Mr. Goodrich two years ago, and have tried them for two seasons. They were the Garnet Chili, the Cuzco, the Copper Mine, and Pink-eyed Rusty Coat. They all have their good points, and are worthy of general cultivation. The Garnet Chili was sent out some ten years since, and is much better known than the others. It is a large red-skinned, white fleshed potato, of very good quality for the table, but not the best, (ranks about with the Davis Seedling,) very productive, very hardy, and yielding few small potatoes. The Copper Mine is a long flattish potato, about as smooth and handsome as the Prince Albert, coppery skin, white flesh, very productive, and of about the same quality as the Garnet Chili. The Cuzco is a white skinned, white fleshed variety, nearly first-rate in quality, and the most productive of the four. I have never found any thing to equal it in this respect. The only objection to it is, a propensity to form little knots upon the tuber, somewhat marring its beauty. The Pink-eyed Rusty Coat is the best in quality, and is so good that it was used in my

family last Winter in preference to any thing else. There is but one potato that I should prefer to it, the Dover, and there is not much to choose between them. It is a large potato, with a rusty brown coat, white flesh, very hardy, very productive, and yielding very few small potatoes. To test their comparative productiveness, I planted upon a two-acre field the following six varieties.

	No. of rows.	Whole yield.	Average per row.
Davis' Seedling.....	26	92 bush.	About 3 1-5th bush.
Prince Albert.....	6	19 "	3 1-6th "
Dover.....	4	8 "	2 "
Garnet Chili.....	18	45 "	2 1/2 "
Copper Mine.....	8	20 "	2 1/2 "
Cuzco.....	6	25 "	4 1-6th "

The land was exhausted meadow, that would not yield ten bushels of corn to the acre without manure. It was manured with twelve bags of fish guano costing fifteen dollars, or seven and a half dollars to the acre. The manure was strewn in the hill. The yield for the whole piece was about a hundred bushels to the acre, which was quite good for so little manure upon so poor land. It is well known that the Davis' Seedling and Prince Albert are among the most productive varieties, and the Cuzco exceeds them by nearly a fourth. This is the general reputation of this potato. Under favorable circumstances, it has been known to yield over five hundred bushels to the acre. A neighbor planted a peck, and with ordinary field culture dug eleven bushels. The productiveness of the Pink-eyed rusty coat is quite equal to the Garnet Chili. This and the Cuzco have shown no signs of disease. The other two have rotted a little under circumstances calculated to develop disease. I regard them all as valuable contributions to our new seedling potatoes, and worthy of general cultivation. If I were to have but one of them, I should choose the Pink-eyed Rusty Coat, on account of its excellence as a table potato. I should put the Cuzco next in quality, and far ahead of the others in productiveness. It makes a very great difference in the profit of raising this crop, whether the yield be one hundred or two hundred bushels to the acre. A very desirable feature in these potatoes is that they are nearly all of merchantable size.

CONNECTICUT.

For the American Agriculturist.

Tim Bunker's Reasons against Tobacco.

"Why don't you use tobacco, and raise it like other people, Squire Bunker?" asked Seth Twiggs one day of me, with a discharge of smoke from his pipe that would have done credit to a locomotive.

"Because you do!" I replied a little gruffly.

"Wal now I don't see the peth of that Squire."

"I do. You see Seth, you and your farm are a standing argument agin tobacco. You are always smoking, smoking, smoking, and you have pretty much smoked your brains out."

"You weren't in any particular danger on that pint, Squire."

"Well I admit I'm not so smart as some of my neighbors, and it becomes me to take care of what little brains I have got."

"Jest so," said Seth. "I see."

"Your eye sight is darkened half the time," I continued "by that cloud of smoke, and you don't know exactly what you're about. You waste time and money as well as brains. It takes you about one half the time to load your pipe, and the other half to smoke it. And it is a great deal worse since you have got them big Dutch pipes, with big bowls and crooked stem, than it used to be when you had that old stump

of a clay pipe that lasted you five years. Then you only put in a pinch of tobacco, and you had to stop in about ten minutes, to take breath and recharge anew. But with these big-bellied things, that hold half a paper of tobacco, you smoke and smoke, and it seems as if you never would stop. You make every place blue, where you go. You go out to feed your pigs in the morning, and it takes you twice as long to do that chore, as it used to. You go into the garden to hoe, and you pay more attention to your pipe, than you do to your hoe. You stop and squirt around every cabbage as if it was covered with lice, and you don't do an hour's work in the whole morning. The weeds get a start of the cabbage, and your garden looks—well I can't compare it to anything else but Seth Twiggs in all the world—*weedy*. You go into the field to work on the tobacco, and the worms get the start of you, and what the worms don't kill, the weeds smother, so that your tobacco fields look worse than your garden. I wouldn't have a man on my farm that used tobacco, at half wages. Now maybe you can see that I don't use tobacco, because you do."

"Yes I see," said Seth, "and Parson Spooner couldn't have said it better. This has been a dreadful season for weeds."

"Season!" I continued, "don't lay it to the rainy season. This thing grows upon you, and laziness goes down into your bones, as smoke goes up into the heavens. You go about dreaming you're making a great stir, and when night comes you find next to nothing done. Tobacco, like wine, is a mocker, and if a man don't want to be befooled, he better not touch it. That is my opinion on tobacco as illustrated in the life and services of Seth Twiggs, the smoker."

Then, to come to the question in the abstract, it is nasty; there is no other word that just expresses it. Don't a man belong by nature to the clean beasts, and what right have I to make myself a nuisance among my kind? It is offensive to every sense. Look into the smoking room of a hotel, or a steamboat, and was there ever a stable fouler?—splashes of juice, ejected quids, cigar stumps, and a reek "that smells to heaven." Won't the world be foul enough without my joining the smokers and chewers?

And it is a very expensive habit. Your tobacco would cost you thirty dollars a year if you did not raise it, and if you take into account your loss of time under the influence of the weed, it costs you four times that sum. You stop to talk with a neighbor, and it makes you long winded, for your brain is so befuddled that you never know when you have done. Many a man spends fifty dollars a year for cigars, and if one has a good deal of company, it is mighty easy to use up a hundred. Your friend, who smokes, never knows when he has enough. He always wants one more of the same sort, and the result is, that your box of Havanas is gone mighty quick, and you can't tell how or where. This makes quite a hole in the income of a man who lives by his hands, or by his brains. I have brains enough to see that I can't afford it.

It is very bad for the health. The doctors are all agreed on this, even those who use it. It don't help digestion. It don't save the teeth. There are better ways of reducing the flesh—eating less for instance. And if the doctors were not all agreed, every man who has his eyes open, can see that no man has sound health who uses it in any shape. They call themselves well, but have headaches, indigestion, don't sleep well, are nervous, have the fidgets, or some other complaints. Occasionally they break down under paralysis. Many make complete

wrecks of their bodies. Always life is shortened. Now what right have I to make an invalid of myself, and go through life sighing and groaning, when I ought to be well? It is worse for a man's mind than it is for his body. It makes him forgetful. He loses the control of its powers, and can't think connectedly. He forgets the names of persons, and places, his own plans, and in short about everything except to smoke. There was our minister, the one we had before Mr. Spooner, smoked himself out of his pulpit. His health failed and his sermons failed worse than his health. They were so foggy that even Hookertown, that never dismissed a man before, could not stand it any longer.

Then it is a bad thing for morals. It begets a great craving for stimulating drinks, and very generally leads to their use, and when a man gets to drinking, he is in a fair way to do almost any thing else. What right have I to endanger the morals of my neighbor, even if I could smoke with entire safety?

Then I have got children and grandchildren, and I think the best inheritance I can leave them is a good example. John would smoke if I did, and I should have more fears of his pipe in the army, than from all the bullets of the enemy. If he dies now, I am certain he will die sober, and without one vicious habit. What right have I to pollute the faces of my grandchildren with the stench of tobacco? I want them to have pleasant memories of their grandfather's home in Hookertown, and I should not feel sure of it, if I scented myself, and my house with tobacco.

Then I am the husband of Sally Bunker, and I think she has the right by marriage vows, to a decent companion in life, with a clean mouth and shirt bosom. What right have I to make a nuisance of myself in her home, to scent her bed with this unsavory perfume, and to befoul her spit-boxes with quids and stumps? I am a little too proud to do that.

And lastly, and to conclude, as Mr. Spooner would say, I expect to give an account of myself hereafter, and if I were to be charged with the use of this weed, I should not know exactly what to say. That fifty dollars a year burnt up and wasted, I think would weigh against me. If I gave it for Sunday Schools, or for any good cause, I should not be troubled about an answer.

Then as to raising this crop, it is a bad thing for the land, affecting other crops injuriously, so far as I have observed. But if this were not so, I could not tempt my neighbor to use what I would not use myself. When I look at Seth Twiggs' farm and my own, I like the contrast.

Hookertown, Nov. 7th, 1863. Yours to command, TIMOTHY BUNKER ESQ.

How Vegetation Influences Climate.

That climate controls vegetation in a great degree, is quite evident, and it is equally true that vegetation itself has a marked effect upon the climate. In the first place, it exerts an influence upon the wind. Where the land is bare of trees, the wind has an unobstructed sweep; and where this prevails, and is violent, the climate is not only unpleasant to man and beast, but is unfavorable to vegetation. Western farmers know how this is, upon their broad, unsheltered prairies, and New-Englanders know how it is along their bleak sea-coasts. The only way to grow handsome and healthy trees in such localities, is first to surround one's farm or garden with a belt of strong, coarse trees, like the willow, silver poplar, and evergreens. Outside of such verdant barriers, the trees and shrubs,

if planted, grow lop-sided, lean, and stunted; inside, they stand erect, well developed, and vigorous. Without this protection there is the unpleasantness of having a gale forever blowing about one's ears, the ceaseless roar of the wind around the dwelling, the rattle of windows and doors, the increased consumption of fuel, and the discomfort of cattle at all seasons, but especially in Winter; put these and the like things together, and we find that whatever serves to break the violence of the wind, or to change its direction, is a thing of considerable importance. It should not be forgotten that air in motion produces more chilliness than the same air at rest. Wet your finger and hold it up in the still air, and you will hardly feel the cold; but swing it around, and the hand will be rapidly chilled. The difference between the climate of a windy region and one sheltered from driving currents of air, is equally great.

Again, vegetation affects climate by limiting evaporation of moisture. Many years ago, Humboldt declared that men in all climates, by stripping the hills of trees, were preparing for themselves two calamities, viz.: the want of fuel and the want of water. The evaporation from trees produces a cool and moist local atmosphere. The overhanging boughs prevent the too rapid evaporation of moisture from the ground, and its dissipation by the wind. The sources of nearly all brooks and creeks are to be found in springs among the hills; and by cutting off the trees which have always overshadowed them, the moisture is rapidly evaporated, and the springs lowered, if not dried up.

Experience is continually demonstrating this. Every old farmer will tell us that his springs are less copious now than they were thirty years ago; and so of the various streams, large and small. The rains fall, perhaps, in nearly their former abundance, but they come oftener in torrents, which sweep down the hill-sides, unobstructed by trees, brushwood, and low vegetation, and pour themselves into the streams of the valley, producing freshets and hurtful inundations; and so we go from freshets to drouths, from heavy rains to long periods of arid, parching dryness. In some parts of Europe, so great harm has followed the destruction of forests, that legislation has been called in to stay their demolition and to promote the planting of new.

Artificial Fertilization of Grain.

Acting upon the supposition that all the flowers upon a head of grain do not produce kernels, a M. Hooibrenck, in France, has made some experiments with a view of helping the process of fertilization by artificial means. The method of doing this is very simple: a rope 20 or 30 feet long, covered with woollen threads so as to form a fringe 8 or 10 inches deep, is drawn across the field, by two men, at the time the grain is in flower. The pollen sticks to the woollen threads, and is by them deposited upon the pistils, which are thus fertilized. These experiments have been examined by a commission appointed by the Government, and the following are given as the results upon equal areas, the size of which is not given. The figures only represent the relative amount of the product:

Rye not fertilized	... 16	Barley not fertilized	... 16
Rye fertilized	... 25.5	Barley fertilized	... 24
Wheat not fertilized	... 21	Oats not fertilized	... 12
Wheat fertilized	... 31	Oats fertilized	... 17

These figures show an increase of about 50 per cent. obtained by a very slight expenditure of labor. Let those curious in such matters repeat the experiment, and report the result.

A SLEIGH RIDE IN THE COUNTRY.

A sleigh-ride! Not a city affair, where a splendid turn-out is hired from the livery stable at five to ten dollars an hour (no uncommon price here), and where you are driven over a mixture of snow and mud, between interminable rows of brick buildings, subject perhaps to the envy of a few who can not afford such a display, and also to the snow-ball peltings of graceless urchins who consider the perpetrators of such absurdity fair game. Nothing of this kind, but a genuine jolly *country* sleigh-ride, suggestive of sleek horses full of mettle, of happy hearts, sparkling eyes, cheeks rosy with an added glow from the bracing air, of inspiring songs and innocent glee, of social visits, renewed friendships, and the twining of yet more tender ties. Such experiences banish dreariness from Winter, and compensate for the absence of the outward glow of the more inviting summer season.

By nature, Americans seem eminently fitted for the highest social enjoyment; they are impulsive, frank, and generous, yet as a Nation, they are far behind some others in realizing the full pleasures of intercommunion. This may be because earnest devotion to business monopolizes attention, and also begets cautiousness, and, if not carefully guarded, jealousy between those who should be neighbors in more than mere nearness of habitation. Winter, with its greater exemption from imperative calls to constant labor, is every way favorable to the cultivation of the social nature. Neighborhood gatherings should be everywhere encouraged, and at the North, the season which makes all the highways smooth, should be prolific in growth of social communion. Let the old, then, as well as the

young, hail the return of the sleighing season, and realize the advantages it brings; let the good fathers and careful mothers remember that their children will be all the more affectionate and teachable, if they enjoy the sympathies of their elders, and that they can be the more surely guided aright by those who preserve the freshness of their own social natures. Bring out the family sleigh, grow young in the revival of old times, and make bleak Winter green with the joyousness of your own hearts.

Some More Humbugs.

A BIG ONE.—Just as our last number was being mailed, we began to receive from various parts of the country, and especially from the distant West, numerous copies of a sheet sent out from N. Y. City, called the "*Freeman's Journal of Science and Medicine*," "Vol. 37, No. 12," (probably the only number ever issued, as it certainly ought to be). This sheet contains a multitude of prescriptions, letters, etc., etc., admirably arranged to deceive the ignorant and unwary, and filch their dollars. It promises untold wealth to those who for two dollars "initiation fee" become members of the "British Metallic Mutual Association." That the scheme takes with a certain class, we have abundant evidence in the letters received, making serious inquiries. They ought to have been able to see the nature of the animal, when "Dr. William Freeman" offers, for \$2, to tell them how to make for \$8 a pound, "a metal that can not be distinguished from California Gold," which will "sell in New-York, London, and Paris, for \$150 a pound;"

and moreover he agrees "to pay \$120 per pound for all that can be made." Of course he would prefer to pay \$120 per pound, rather than to make it himself ("easily" as he says) at a cost of only \$8. The paper is ingeniously got up, but it is all humbug. If Dr. Freeman would only tell people, or tell us, where he might be found, we would straightway call upon him. We should like a hand in some of his enterprises, if the hundredth part he says is true, for we could make money ten thousand times faster than in publishing the *American Agriculturist* at \$1 a year, with printing paper getting towards a quarter of a dollar a pound. But his only advertised place of business in New-York City is just 4 by 6 by

10 inches—a large establishment, viz.: "No. 5153 Post Office" Street. The above is all the room we have for you, Mr. "Dr. Wm. Freeman," of the "British Metallic Mutual Association," and we hand you over to Mayor Opdyke.

THE GOOD SALARY HUMBUG.—Our country friends will very often see fine openings for young men in the city, especially those who have a few hundred dollars to invest. Let us tell them, once for all, that 999 in every 1000 of these offers are humbugs. We give two illustrations: A few days ago an "Employment Agency" advertised for a clerk in an oil company in Pa., at \$800 a year, etc. A young man just over from England applied, and was told that for \$6 he could secure the place. He paid the money, or so much as he had, and was told that the President of the Company was coming to the city on the following Monday, and would call for him. The young man called on Monday, but found no one in (probably fifty others had paid for the same place and were told to call in the same way, but on some other day or hour.) The young man called again and again, and finally watched the door all one day, and at last caught the swindler in. He plead absence from sickness, and showed a (bogus) letter from the "President," saying he had been detained by important business but would come soon. The young man called day after day with the same result, and finally becoming impatient, used some harsh words, when the man ordered him out, threatening that if one word more was said he would have him arrested for assault, and swear him into prison. The swindler had found that his victim was a timid stranger, and got rid

of him thus; and by similar subterfuges he probably pocketed \$500 from a hundred victims, in less than a month; and thus the game goes on. The victims are strangers; their first experience makes them afraid to trust anybody, and they refuse to appear even as witnesses if any one happens to find out their case and offers to aid them.—The following letter explains itself:

To the Editor of the American Agriculturist:

As a warning to others, allow me to give your readers a little of my experience, if you suppress my name. I am a farmer's son of Western New-York—have devoted most of my spare hours to books, and learned but little of the 'ways of the world.' I came East to college with but a small sum to carry me through, and by boarding myself and earning what I can in vacations, hope to complete my course. As the winter vacation was approaching, I was casting about for something to do, when I saw the following advertisement published in a New-York Daily Paper:

"A GOOD CHANCE FOR A YOUNG MAN."—A fine exhibition of works of art is nearly ready. A young man is wanted for the Winter to assist in explanations and in attending at the door. One preferred with \$300, to be used under his own direction, in completing some final purchases of materials which he can retain until reimbursed. As security, he will have charge of the exhibition works, which are worth \$3000, and he will also have the care of all the money receipts. Salary \$100 a month and expenses, or if preferred, a part interest. Call on, etc."

As I had just \$300 left, this seemed to be a good opening for me. So I hastened to New-York, and called as directed. I found a very bland man, who was exceedingly patronizing, and who, under the plea of learning my qualifications, drew out my personal history. He decided I was just the man wanted. He showed me a printed handbill (but I could not get a copy to keep,) setting forth a magnificent exhibition. He made very ingenious excuses for not showing me the works that day, and for wanting the money at a given time. On my insisting upon seeing them, he took me into one of the largest Picture Galleries, and named a dozen fine paintings as belonging to his outfit, which (he said) had been left there temporarily by special request. On my pressing him further to show me the chief objects, he led me around through several streets, and finally stopped before a large building closed up. He knocked violently but no one answered; he went round the building hastily, and soon after came back with the statement that his artists had all gone off on a target excursion without mentioning it to him. He then went into a rapturous description of what was inside of those closed doors. On our way back, he invited me to dinner at a splendid saloon, and on going out, felt for his pocket book to pay, but unfortunately he had "changed his pants, and left his purse"—wanted me to pay, and he would settle it at his room. I stood it, but my eyes were open by this time. I had two hours before the evening boat, and during this time he exercised his utmost ingenuity to get a bonus towards the \$300 (which I did not refuse to pay, until I felt myself safely out of his influence.) At last, when about to start, I told him I should keep my money. He then went off into a very high strain of injured innocence—accused me of using up his whole day, and demanded \$10 for his time—"a hundred dollars would not pay him." He claimed I had agreed to invest the money early in the day, and called upon an apparently unconcerned man, who had been near us several times, who at once said he would swear I did positively agree. The two tried hard to scare me out of \$25, then \$10. I was a stranger in a, to me, strange city, and felt a little nervous, as I hardly knew the way to the steamboat. One of them started off saying he was going round the corner for a warrant, and that I could not leave the city until I had made it right with him. I started, however, one of them following me, crowding me and trying to frighten me. Seeing a policeman I quickened my steps and called for his protection. Just then the chaps disappeared round the corner, and I got to the steamboat, arrived at my room the next morning, minus two days time, and \$9 expenses, but a much wiser young man. I give you in outline, a statement of facts—hoping others may become wiser at less expense.—Yours, &c.

HUMBUGS NOT IN NEW-YORK.—Before us are copies of a most ingenious and taking circular, being scattered to distant points, from Biddeford, Maine, which is well calculated to deceive the unwary. The matter is under investigation, and promises amusement if not instruction to our readers. We confess we formerly had, as a country farmer, a little experience in being humbugged. This, with the lawsuits commenced and threatened as an intimidation, by those shown up, adds zest to our labors in this line. Farmers, as a class, have honest aims and intentions, and are therefore less suspecting

of fraud in others: we therefore consider it a part of our legitimate labors to specially guard them, by frequent examples of *how* the humbugs operate, and shall continue the practice. The exposures in the *Agriculturist*, during several years past, have undoubtedly saved our readers, as a whole, many times as much money, as the entire cost to the country of issuing this journal.

The "New-Jersey Tea."—A Caution.

This plant has been noticed in various papers as "Pennsylvania Tea," "Alleghany Tea," and "American Tea," and it has even been claimed that it is the identical Chinese tea plant, discovered here in America. We have already shown what the plant is, in the September *Agriculturist*, page 265. As it has been long and generally known as New-Jersey Tea, we prefer to continue to so call it, rather than to apply a new name to a well known plant. A company claim to have secured a large tract of land in Pennsylvania where this plant abounds, and intend to prepare the article for market. In the leaf simply dried we are not able to detect any strong resemblance to tea, but when prepared by drying by heat, and rolling after the manner of the Chinese, it has, partially at least, the odor and taste of tea. A sample which was thus prepared in a rough way, we tried as an experiment, and found it made an infusion resembling that of the lowest priced imported tea, and, if properly made, it may perhaps prove to some extent a sort of a substitute for teas of this class. If low-priced tea—or what will answer its purpose—can be made from one of our native plants, we shall be glad to see it done, as it will open a new avenue for industry, and by producing, on our own soil, an

Fig. 2.—NEW JERSEY TEA.

very appropriately characterizes it, "hosh." The whole thing is an experiment, and should succeed or fail on its own merits. We repeat that the plant is *not* the Chinese Tea, (*Thea viridis*, at all, nor does it resemble it either in ap-

Fig. 1.—CHINESE TEA.

article for which large sums are annually sent abroad, it will be a national benefit. The circular of the company above alluded to, which has been distributed among capitalists, states that this is the 'Tea plant,' thereby conveying the impression that it is the same as the Chinese plant. This is simply absurd, or as the London Garden-

ers' Chronicle very appropriately characterizes it, "hosh." The whole thing is an experiment, and should succeed or fail on its own merits. We repeat that the plant is *not* the Chinese Tea, (*Thea viridis*, at all, nor does it resemble it either in ap-

pearance or botanical characters, but is the "New-Jersey Tea" (*Ceanothus Americanus*). It is not confined to any particular locality, but is common in all the northern States, though it may grow more abundantly in some localities than in others. We have stated that the infusion of the leaves had somewhat the taste of tea; whether it will have the refreshing and stimulating qualities of the foreign article, or whether it can be made a constant drink without causing derangements to the system, are facts which can only be determined by experience. The American Tea Company claim that the article can be delivered in the market at eleven to thirteen cents per pound. In this case there will be a strong temptation for dealers to use it in adulterating the imported article. That our readers may be on their guard against this, we give a drawing of the leaf of the Chinese Tea, and one of the New-Jersey Tea. By carefully spreading out the larger pieces from the "grounds" left in the tea-pot, the shape of the leaves can be made out. It will be seen that the Chinese leaf is narrow at the base or lower part, and that the strong veins run together near the edges of the leaf, and make a series of loops. The New-Jersey leaf is wider at the base, and has two strong veins which run nearly parallel with them near the edges, and are nearly straight, not making the looping, shown in the other.

Mildew and Rot in Grapes.

These subjects were discussed at the annual meeting of the East Pennsylvania Fruit Grower's Society, with the following result: "That it is the experience of this Society that mildew on the grape is principally atmospheric, and that shelter and protection are the only expedients known at present, that seem to offer an exemption; and that although the soil may influence the general vigor and health of the plant, and thus render it more liable to disease, yet it is not the prime origin of mildew. That the rot seems to depend more particularly upon the nature of the soil. That vines on open porous soils are less liable to rot, that heavy manuring and excessive enriching favors rot; and that clayey subsoils are 'particularly pernicious.' The statement that mildew is 'principally atmospheric' is a very vague one. Mildew is a minute parasitic plant of the fungus or mushroom family, which lives upon the tissues of the leaves, and causes their decay. The Society probably meant to say, that the growth of this parasite was favored or retarded by the condition of the atmosphere.

Notes on Grapes.

In our remarks upon the grapes exhibited at the Grape Show, the *Union Village* was passed with rather weak praise. Since then Dr. J. B. Chapin of Rhode Island has sent us a specimen of the fruit thoroughly ripened, showing that, with him at least, it attains a perfection we did not suppose it capable of. It is generally the case that black grapes color sometime before they are really ripe. This is illustrated by the *Isabella*, which is seldom found in the market well ripened. If the *Union Village* can be grown elsewhere, as fine as those sent by Dr. Chapin, we shall rate it much higher than heretofore. In size and beauty it is hardly excelled by any of our natives, and not surpassed by the *Black Hamburgh*.—*Diana*. This variety is remarkable for its keeping qualities. A collection of about 20 varieties has been exposed upon our tables for some two weeks, and while most

of the others have become shriveled and unsightly, the Dianas remain plump and fresh. Good judges place it high as a wine grape, and consider that a mixture of this and the Delaware produces better wine than can be made from either variety alone. Elsinburgh and Herbemont.—These small grapes grow in favor as they become better known. They will probably never be popular as market fruit, but for the table we consider them very fine. The berries are scarcely larger than good sized peas, but they have such a sprightly vinous flavor that they are great favorites with many. The Elsinburgh is the more hardy of the two. Though these grapes are much alike in size and general appearance, they differ in sweetness and flavor, and are both desirable in amateur collections.

Origin of the "Clinton Grape."

In his address at the Kirkland Agricultural Fair, Prof. North stated that the Clinton Grape originated in the horticultural amusements of a student at Hamilton College, and that the original Clinton vine is now growing over a tall elm tree near the house formerly occupied by Dr. Noyes. It was planted there in 1821, by Hon. Hugh White, of Cohoes, who was then a Junior in College. Two years before, he had planted a quantity of grape-seed in his father's garden in Whitesboro'; and out of the hundreds of seedlings that grew up from this planting, one was selected that looked promising, and was planted near the house of Dr. Noyes, with whom Mr. White then boarded. It proved to be a rampant grower, and wonderfully productive. As a grape for making wine and jellies, it has come to be a favorite in latitudes where the Catawba will not ripen. It is a somewhat popular grape with those who make no special objection to a little foxiness, because the vine is so thoroughly hardy, and the crops so unfailing. The original Clinton grape-vine now girths fifteen inches for each of its main branches.

Mr. L. B. Langworthy, in a communication to the Rural New-Yorker, claims to have first introduced and named the Clinton, and that it originally came from a farm in Waterford, on the Hudson River. As Mr. L. did not know the vine until 1830, while Mr. White planted his in 1821, it is possible they may both be the same. Mr. Langworthy invites an interchange of specimens to settle the question of identity.

Keeping Grapes.

J. S. Christian communicates to the Prairie Farmer the following plan: The grapes are picked when fully ripe, on a dry afternoon, and taken to a dry cool room where every unripe or decayed berry is removed by means of a pair of scissors. The bunches are laid out so as not to touch each other, and allowed to remain for three weeks, until the stems are thoroughly dry. Tissue or soft printing paper is cut into pieces of a size to envelop each bunch. The square of paper is laid on the left hand, a bunch of grapes is laid upon the paper, and the edges of the paper are brought up over the bunch and secured by twisting the ends. The bunches thus enveloped are laid in boxes deep enough to contain two tiers. The boxes are covered and kept in a cool room. If there is danger of frost, they should be covered with carpets or quilts. Isabellas, Dianas, and Delawares, may be kept in this way until Spring, in a perfectly fresh state.—*Query.* Will the grapes keep well when thus left three weeks in the open air?

Labels for Fruit Trees.

"Shady Side," of Pittsburg, Pa., thinks that the leaden label described in the *Agriculturist* for October, may be good, but he prefers a label of sheet zinc which has a hole punched at one end to receive a piece of copper wire by means of which it may be attached to the tree. The name is written upon the label with a common pen, and with an ink made as follows: 1 drachm each of verdigris and sal ammoniac, $\frac{1}{2}$ drachm lampblack, and 10 drachms of water. This can be prepared at any drug store. The recipe is not by any means new, and we give it for the benefit of those who may not have seen it. The advantage of the sheet lead label is, that it yields to the growth of the tree and there is no danger of that strangulation which is often produced by copper wire, when neglected, as it often is. The zinc labels might be fastened on with lead wire, which is sold at the agricultural implement stores. In the engraving of the lead label published in October, the end passing through the slit should have been bent over in order to properly secure the label.

Prepare the Vegetable Garden.

In December there is often a mild spell in which preparation can be made for Spring in the garden. A deep soil is essential to the production of garden vegetables; but if the soil is unfortunately shallow, and with an unfavorable subsoil, measures should be taken to deepen it. Works upon gardening, presuming that the soil is of course deep, direct trenching. In this operation, properly performed, the ground is dug at least two spades deep, and the lower soil brought to the surface, and the upper soil put in its place below. There are many gardens in which it would be decidedly poor management to bring a poor subsoil to the top, and to bury the good surface mould a spade deep. Where the soil is shallow, the aim should be to increase its depth and better fit it for the growth of those plants the roots of which penetrate deeply. In small gardens this work can be done with the spade and at this time of comparative leisure, provided the ground be not frozen nor too wet. The usual method of working is to dig a trench about three feet wide and a spade deep, throwing out the soil on one side; put a good supply of manure into the trench, and spade it well into the subsoil at the bottom. This being done, commence a second trench close to and parallel with the other, throwing the top soil into the first trench, working in manure at the same time. The subsoil in the second trench is treated the same as that in the first one, and the work is continued by making trench after trench, and manuring each one in the same way. The top soil of the first trench is finally put into the last one. The

d					c	a	b
e							f

accompanying diagram will show how the work may be laid out so as to avoid the fatiguing labor of wheeling the earth taken out of the first trench to the last. The spading is begun at *a*, the dirt being thrown out at *b*; this trench being treated as above directed, and the work continued until *d* is reached. The top soil from *e* is thrown into *d*, and the other half of the plot is then spaded over and treated

in the same way, and the job finished by putting the earth thrown out at *b* into *f*. If the garden is of sufficient size, it should be so arranged that the greater part of the labor can be done with a horse. It is a great saving to substitute the plow and cultivator for the spade and hoe, and to do this requires a little forethought. All those plants which remain in the same spot for several years, such as asparagus, rhubarb, and the perennial herbs, should have a location by themselves; the remainder of the garden, which at most needs but a single path through the centre, will then be left unobstructed. It is a great waste of space to cut large vegetable gardens into beds, as it costs about as much labor to keep the paths clean as it does to cultivate the crops. Gardens laid out in beds and edged with box or other edging, may look very neat, but they are unprofitable. Every crop, the nature of which will admit of it, should be planted in rows sufficiently wide apart to allow of cultivation with horse power.

Manuring Pear Trees.

At one of the Fruit Growers' Meetings, Dr. I. M. Ward, of Newark, N. J., gave, by request, an account of his manner of manuring his pear orchard. In Autumn he applies several barrow loads of course stable manure to each tree, spreading it several inches thick all around the tree as far as the roots extend. During the Winter the soluble matter is gradually leached from the manure and carried into the soil. In the Spring what remains of the manure is covered with a coating of salt hay (or any other cheap hay) and it is allowed to remain on until Fall, when it is removed, and manure applied as before. By having the ground mulched in this way, it is kept moist and free from weeds. This mode of applying manure is approved by some of our most successful cultivators, and is preferred to plowing in the manure, at the risk of disturbing the surface roots.

Fruits for Eastern Pennsylvania.

Frequent inquiries come to the *Agriculturist* as to what fruits to plant. These we answer when we have the statistics at hand. The very local character of many of our fruits is not generally appreciated. What will succeed in one place will sometimes fail in an adjoining town or county. The knowledge of the geographical characters of fruits is yet very imperfect, but each year is adding to it, and we watch with much interest all the reports of discussions of horticultural societies, farmers' clubs, and the like. At the Fruit Growers' Society of Eastern Pennsylvania, the following were decided upon:

Summer Pears.—Manning's Elizabeth, Doyenne d'Été, Tyson.—*Autumn Pears.*—Bartlett, Seckel, Belle Luerative, Beurre Diel, Beurre d'Anjou, Louise Bonne de Jersey, Sheldon.—*Winter Pears.*—Lawrence, Vear of Winkfield.

Strawberries: Wilson, Triomphe de Gand, Fillmore, Jenny Lind, Lady Finger.—*Raspberries:* Purple Cane (earliest and best), Brinkle's Orange, Franconia, Hornet.—*Blackberries:* Dorchester, it being preferred to the New-Rochelle, as being sweeter and earlier.

HOW TO LAY UP MONEY.—Always spend each week less than you receive. Our real wants are always less than our desires. The writer has lived on two shillings a week for eatables, for months together, living on hominy and milk,

and enjoyed as good health and spirits as when eating up what costs thirty times two shillings. He modified his desires to suit his income, and has now "something for a rainy day."

Cranberries on Upland.

From the fine specimens which have been exhibited this season, our hope that Cranberries may be successfully grown in common garden soil is increased. The tables of the *Agriculturist* have now several samples of the fruit grown upon dry land, which will compare favorably with any produced in bogs. One specimen, remarkable for the high color and beauty of the berries, was grown upon the pine barrens of Long Island, by T. E. Bridger. The lands were cleaned and broken up, and planted with roots taken from a natural bog. The plants have now been out for three years, and produced at the rate of 75 bushels to the acre. Another fine specimen is from W. I. Spence also of Long Island, who shows a potted plant to illustrate his manner of growing the vine. Mr. S. keeps the runners clipped off, and induces the plant to grow in a bushy form. The plant exhibited, is a miniature tree perfectly loaded with fruit. Experiments continued through several years are needed to determine if the vine will do well under this treatment. Recently, we saw a patch set out in common garden soil with the addition of a dressing of sand. The vines had been planted but two years; from their strong growth they looked as if they would be a success. It will cost but little trouble to make the experiment of growing cranberries in the garden; the plants can always be procured from those who grow them for sale. We have some hope that garden culture will prove so successful that the cranberry patch will be as common and as indispensable as the strawberry bed.

Collect a Store of Leaves.

There are loads of excellent manure being blown about by the winds or hidden in the forest, which should be made available in the garden. If the snow has not covered them, the leaves may yet be secured. It is but little work to gather a large store of them from the woods, while those which disfigure the lawn and collect in the fence corners should be very carefully saved. They are best preserved under a shed, or they may be made into a heap upon which some boards are to be placed to keep them from blowing about. Leaves are an excellent mulch for strawberries and other plants, but require to have brush laid over to keep them in place. One of their most important uses in the garden, is in the making of hot-beds in Spring. Used in equal quantities with stable manure, a more manageable and lasting heat is obtained than with manure alone, and when the hot-bed is done with, there will be left a mass of most excellent compost. Leaves may be used to increase the stock of manure by putting them into the hog-pen, barn-yard or compost heaps.

How to Fumigate a House Plant.

Bessie W., wishes to know how she can destroy the aphids or plant louse upon her roses and geraniums. We have found tobacco smoke to answer the purpose. Coil up a newspaper or other large paper in the form of a cone, pin it so that it will keep its shape, and invert it over the plant. Then if you happen to have some friend at hand who smokes, get him to

light a little tobacco in the bottom of the bowl of a common pipe, and when this is well kindled, fill up the pipe with tobacco. Then introduce the bowl of the pipe under the edge of the paper cone and blow through the stem. The fire being at the bottom, there will be copious clouds of smoke driven into the cone. If no smoking friend is at hand, you may manage it yourself, by putting a small live coal at the bottom of the pipe, place the tobacco upon it, and proceed as before. Care should be taken not to drive the hot smoke from the pipe directly against the leaves. Let the plant remain 10 or 15 minutes in the smoke, and then lay it on its side in a sink and give it a thorough drenching from a watering pot.

Hints about House Plants.

There is quite a pile of letters upon our desk from persons who have written to the *Agriculturist* complaining of their want of success in growing this or that house plant, and asking for advice. These letters we shall be obliged to answer in general terms. The great difficulties in growing plants in the living room are: the excessive dryness of the atmosphere, too much heat and too little light, the great alternations of temperature, and improper watering. There are a few plants which will stand any treatment and neglect, but most of the choicest varieties must have some care in respect to the conditions above noted. In Winter the air of our living rooms is too dry for the healthful condition of either animals or vegetables—especially when the house is heated by a stove or a furnace. Now, unless we can avoid excessive dryness by evaporating water, either on the stove or in the furnace, there is but little use to try to cultivate house plants. An atmosphere, not unnaturally dry is one of the first essentials.

In many of the rooms where plants are grown, there is an almost tropical heat and very little sun. Under such conditions it is in vain to expect a healthy growth. The plants, to flourish well, must have the sunlight; the morning sun is preferable, but the afternoon sun will do. Plants will survive if kept in diffused daylight, but will not be vigorous unless they have direct sunlight during some part of the day. Another great drawback to the growth of plants, is the serious changes of heat to which our dwellings are generally subject. During the night the temperature is allowed to sink nearly to freezing, and in the morning when the fires are built, it is suddenly raised to over 70°. These daily alternations are very severe upon the health of the plants, and only the most hardy can endure them.—If all conditions of temperature and light are satisfactory, still the plants will not grow unless properly watered. House plants are liable to suffer both from a lack of water and a superabundance of it. All glazed pots or porcelain jars should be discarded. There is nothing so well adapted to the growth of plants as the common clay pot or crock. Nor should these be, as is often the case, kept standing in a saucer or feeder of water. The saucers may answer very well to keep the pot from contact with the shelf or stand, but as a receptacle for water it is worse than useless.—Too much attention can not be paid to potting. The pot, if of medium size, should have at least an inch of broken crocks placed in the bottom before the earth is put in, to afford the soil ample drainage. The proper amount of moisture for plants is just what can be held by the soil where it has free chance to drain off. If the pots are

well drained, the plants may be watered freely, and the excess will run off through the holes at the bottom. In warm rooms, plants will generally need watering every day; this is best done with a watering pot, which will distribute the water evenly without disturbing or packing the earth. The water applied should be at least of the temperature of the room. It is a serious check to plants in an atmosphere of 70°, to give them water at 40°. The water should be kept long enough in the room to acquire its temperature, or be brought up to that by the addition of hot water. In house rooms the foliage soon gets covered with dust, which not only injures its appearance but seriously impairs its health. All smooth leaved plants will be much benefited and their appearance greatly improved by carefully wiping their leaves with a damp sponge. Those which have hairy leaves and can not be treated in this way, should be placed out of doors on a mild day, and syringed or showered; or, if the weather will not admit of this, they may be placed in a sink and there receive a drenching. The plants should have plenty of air on mild days. By observing these hints, our readers will have less cause to complain of their want of success with house plants.

Spring Flowers in Winter.

Several favorites of the garden can be had in flower during the Winter, by taking a little pains. The Dicentra, Lily of the Valley, Deutzia gracilis, and many other hardy plants may be made to serve as ornaments in the parlor or sitting room. The plants taken up before the ground is frozen, and potted, will make a tolerable show, but some will flower much more finely if they are allowed to make their first growth in the dark and are then brought to the light. The Lily of the Valley, if judiciously treated, may be made to show its beautiful and fragrant flowers by Christmas. The following directions for forcing this charming plant are condensed from Rand's excellent little work, called "Flowers for the Parlor and Garden." After the middle of November the oldest tubers are taken up, being careful to select those which have thick blunt buds, as these alone produce flowers. The tubers are wrapped in a little moss and packed as closely as possible in pots or boxes, filled with light porous soil; they are planted just deep enough to cover the buds. An empty pot, or box, of the same size is inverted over that in which the plants are placed, and the whole set in a warm place, and it is all the better if they can have a little bottom heat, which can be given if one has a greenhouse. The plants are kept in this way in the dark until they begin to show flowers. The pots may then be transferred to a light room, or the plants may be placed in vases or in baskets, where they are to flower. By bringing them gradually into the sun-light, the leaves will soon turn green. Of course as soon as the plants start, they should have a supply of water. The Dicentra may be treated in the same way, and we know of no more beautiful plant for forcing. The Deutzia gracilis, from its small size and neat habit, is one of the best shrubs for winter blooming. Take up the plants with a ball of earth and place them in a cool cellar, and when wanted for flowering, pot them and bring them into a warm room. Plants forced to bloom in the Winter, cannot be expected to flower again in Spring. They may be planted out and allowed to recover, or if there is already an abundance, they may be thrown away.

Notes on the Basswood or Linden.

A note in the *Agriculturist* for June, upon the preparation of basswood bark, has called out inquiries as to the characters by which it may be recognized, and the manner of its growth. As the tree grows from Canada to Virginia, and southward, it is probable that most persons who live in the country are somewhat acquainted with it. The botanical name of the tree is *Tilia Americana*, and it is known by the popular names of Basswood, Linden, Lime-tree, and White-wood—the last name is, however, in some regions exclusively applied to the Tulip-tree. When allowed to grow by itself, the Basswood forms a large tree of a very regular form, and in the density of its shade, is equalled by few of our native trees. The bark of the young trees is very smooth, and that of the young shoots is of a very dark color. The leaves are roundish, heart shaped, with one side larger than the other, sharply serrate—rather thin, and about 5 inches long and wide. The flowers, which appear in July, are in clusters upon a long stalk, are yellowish white with a very pleasant fragrance. The flower stalk has a long leaf-like bract or scale attached to it for about half its length; this alone will, in the flowering season, distinguish it from any other native tree. The fruit consists of a round gray nut, about the size of a large pea, which contains a single seed, and is ripe in October. The tree will grow in poor soil, though it delights in a fertile one, and is valuable as a shade tree. The European Linden is often planted for this purpose, but the native species is preferable on account of its greater freedom from the attacks of insects. The flowers are much liked by bees, and the honey which they furnish, is said to be finer flavored than any other. The use of the inner bark is well known to all who work in the garden, its flexibility and great toughness rendering it the best possible material for tying. It is largely used in northern Europe for making mats, cordage, fishing nets, and even coarse clothing. The Russian mats furnish the main supply of tying material to our gardeners,

though a superior article can be made from the inner bark of our native tree. The bark from the tree, cut any time during the growing season, and treated as directed in the June *Agriculturist*, will give a most excellent material for tying. In localities where it is not found native, it would pay to cultivate the tree for this purpose only. Trees of a foot or less in diameter are preferred to larger ones, for furnishing bark. The wood is tough and pliable, and is used by wagon builders for panels, by cabinet makers for drawers, and by stair builders where the work has to be curved. The tree is readily raised from the nuts, which are planted in the Autumn, or kept through the Winter in boxes of earth. The young plants are left for two years in the seed bed, they are then taken up, the roots shortened, and the side branches trimmed up and set in nursery rows where they are left until large enough to be planted where they are to remain. The tree is also propagated by layers. When a tree is cut down, numerous shoots spring up from the stump; these at two years old, are layered in Autumn, and at the end of a year will be well rooted, when they may be removed. The engraving represents the flowers and smaller leaves, with fruit of the natural size.

A JACKET TO KEEP OFF BORERS.—Geo. T. Leach, Litchfield Co., Conn., uses a strip of White-birch bark 3 or 4 inches wide and long enough to go once and a half around the tree to be protected. The soil is removed and this is wrapped around close to the roots and the soil replaced. Mr. L. says that he never knew a tree thus treated to be harmed by the borer. Any wrapping which can not be penetrated by the young borer will answer a good purpose, and where birch trees are plenty the bark may be used instead of wrappers of strong paper, cloth, and other materials, which have been recommended. We suppose that our correspondent means the Canoe-birch rather than the White-birch. A gentleman in Connecticut informs us that he saved his peach trees by a mound of stones around the trunk to prevent the parent of the borer from depositing eggs near the root.

The Growth of Pear Trees in Hedges.

Allusion has been made to this way of growing the pear, and those who have tried it, are enthusiastic in its praise. Mr. T. W. Field of Brooklyn has a large number of the Duchesse in hedges; he thinks this variety particularly adapted to this treatment, and is convinced that he can get larger crops of fruit than can be obtained by any other mode of culture. Dwarf trees are planted two and a half feet apart, and are clipped yearly, like any other hedge. Such a hedge would make a very pretty boundary to a fruit garden. Mr. Field cultivates the trees in this way for the fruit, and his hedges are parallel with each other at a distance of only 4 feet. Mr. J. C. Thompson of Staten Island is cultivating a hedge of Bartlett's, but he follows a different method. The trees are five or six feet apart; the branches are allowed to grow upright at first, and are gradually brought to the horizontal position by bending them down and tying them to the neighboring trees by means of strings. Low branching trees are to be selected for this purpose, and if they do not branch sufficiently low, or if a branch is needed to fill a gap, a twig is inserted by side grafting; or, if a dormant bud is found in the right place, it is induced to start by notching the bark just below it. Grown by Mr. Thompson's method the tree is like an espalier without a trellis. The bending down of the branches causes the formation of fruit buds along the whole length. We never saw a greater promise of fruit than these trees present, and shall watch their future growth with interest, and report the result.

A New Squash—The Yokohama.

Thomas Hogg, Esq., the well-known horticulturist, now in Japan, sent from that country to his brother here, Mr. Jas. Hogg, some squash seeds which were planted and carefully cultivated at a distance from any other variety. The vines proved to be very robust and vigorous, running freely, taking root at every joint; they bore a large crop of squashes so different in appearance from anything we now have, as to mark it as a new variety. The engraving, fig. 1, will give an idea of its shape. It is about 8 inches across, 4 inches thick, and weighs from 6 to 8 pounds. The stem instead of being round and fleshy as in Hubbard and other fine fleshed squashes, is very long, woody, and angled

Fig. 1.—YOKOHAMA SQUASH.

like that of the pumpkin. The surface is strongly ribbed; the skin warty, and of a dark green color, which frequently turns more or less completely to a dull orange. The cavity for the seeds, as seen in fig. 2, is very small and placed near the blossom end, where the flesh is very

thin. Seeds very small, not larger than those of the summer crook-neck. We have cooked this squash in various ways, and consider it of the first quality. The flesh is very fine grained, sweet, sufficiently dry, and good flavored. It has

Fig. 2.—INTERIOR OF SQUASH.

the appearance of being a good keeper, but in this respect it is yet to be tested. From the size of the seeds, Mr. Hogg supposed it to be a bush-squash, and planted it so closely that the vines did not have a fair chance to run, but in this unfavorable condition it proved to be a good bearer, and much earlier in maturing than other Autumn varieties. We suppose the small stock of seeds will be placed on sale with some of the seed dealers; we have none to dispose of.

A Convenient Clothes-Sprinkler.

A subscriber to the *American Agriculturist*, Geo. L. Hale, Cumberland Co., Pa., sends a model and description of the clothes-sprinkler illustrated herewith, which we find upon trial to be a convenient instrument. It is made of tin, the main part or cylinder, $4\frac{1}{2}$ inches long, and $3\frac{1}{4}$ inches in diameter. One end is convex and is punched with very fine holes, $\frac{1}{2}$ inch apart. The handle is $4\frac{1}{2}$ inches long, hollow, and opens into the cylinder. When in use, the top of the handle is closed by a well-fitting cork. To fill the sprinkler, take out the cork and plunge the cylinder into a vessel of water; then insert the cork, and with a gentle shake, the water will be thrown over the clothing more evenly than can be done by the hand alone, and without necessity of wetting the fingers. The article is not patented, and can be very easily and cheaply made by any tinman.

CLOTHES SPRINKLER.

Economy in the Household.

With cotton cloth at 40 cents a yard, chickens at 18 cents a pound, and beefsteak not much less—with every article of food and clothing greatly increased in price, there is need of economy, especially among that large class, having fixed salaries and incomes. The war or something else has greatly increased the expenses of living, without adding to the income of a large class of the people. The laborer and mechanic have raised the price of their wages very properly, perhaps not in proportion to their increased expenses. But the doctor does not charge any more for his visits, the lawyer probably thought that he charged about enough before, and the people seldom think of raising the minister's salary, 40 or 50 per cent., to enable him to make both ends of the year meet. The board of directors in the bank have not increased the salary of the cashiers and clerks, and the grocers and dry-goods men have forgotten that the board and clothing of their employees have advanced a third or more. (Though printing paper costs double now, the subscription price of this journal is not increased at all.) With the general prosperity of the country, there is a good deal of pinching in spots.

What is to be done to meet the emergency? The hardest matter, perhaps, is to get rid of a little pride, and adapt ourselves, with true manliness, to our new circumstances. An old coat, if it be clean, is handsomer upon an honest back, than the most splendid garment a bankrupt ever wore. In these days of cheap benzine, (there is one thing cheap,) a little money will go a great way in removing grease-spots and renovating an old garment. We must wear our garments until, like the deacon's *one-hoss shay* celebrated in Holmes' muse, they fall to pieces of their own weight and antiquity, or rather until the day before that catastrophe. We shall have less to sell to shoddy manufacturers, but they will make enough without our patronage. Then, in taking care of the stomach, we must go in for the substantial rather than the most costly and fashionable dishes. If flour costs \$11 a barrel, do not buy a poor article of flour, but use more Indian and rye meal instead. Look back over the *American Agriculturist* recipes for cooking corn meal; one must be hard to suit if he does not find dishes good and cheap. A dollar in this article will go as far in sustaining life as \$2 in fine flour. Rye makes an excellent bread, and is much cheaper than wheat. The unbolted wheat commonly known as Graham meal, makes a very wholesome bread.

If sugar is \$40 a barrel, use less of it. Substitute sweet apples for the prepared sweetmeats, and both money and health will be saved. It is not necessary, at every evening meal, to have preserved quinces, peaches, or strawberries, that have been made with a pound of sugar for every pound of their own weight. Baked apples, with a little milk, disappear with celerity. If coffee is 50 cents a pound, barley is only 2 or 3, and the latter is the more nutritious article, and makes a very fair drink. If tea is a dollar, use water, which is both cheap and wholesome. You will soon get accustomed to it, and find that it agrees well with the nerves. "But would you have us starve to death in these hard times?" Not at all. The country is too much in need of every good citizen to lose one, by under or over-feeding. We must have good wholesome food, and that which is enjoyable. When beefsteak is 18 cents a pound, it is not necessary that every meal should come out of the sirloin. A shin-bone costing a quarter as much, made into a soup, will dine quite as large a family, and give them as much strength for physical or mental labor. We are greatly behind our neighbors, the Germans and French, in the use of soups, and indeed in all matters of economy at the table. With the same income they will live comfortably and save, where we should feel pinched and run in debt. The war is working out good results for us, in many respects. It will be one of its greatest blessings, if it teach us simpler modes of living, and constrain us to a more healthful use of the bounties of Providence.

TAINTED BARRELS.—A. Neep, Ohio, says: "Fill the barrel with hay, then fill up with boiling water, let stand for 24 hours, and the thing is done." We have seen hams, which during a long overland journey in a warm country, had acquired an unpleasant odor, rendered perfectly sweet by putting them for a day in a tub with hay and cold water. "Wm. L., Orange Co., N. Y., directs to fill the cask with sour milk or whey, let it stand several days, then refill with water, and change occasionally.

Pattern for Crocheting or Netting a Tidy.

The above pattern, designed for the *American Agriculturist* by Miss Sallie R. Bowman, Philadelphia Co., Pa., is intended for crocheting, or for darning a netted tidy. Those skilled in the mysteries of such fancy work will have little difficulty in making an enlarged copy to work by; or by noticing the arrangement of the small squares, the design can be followed directly from the engraving. As will be generally understood, the smaller figures at the top are samples of the border and corners. The space left between the chief ornament in the centre and the border will be regulated by the size of the tidy and the fancy of the maker.

A Home-made Toast Holder.

This simple contrivance will be found a very convenient article, particularly for those who use coal fires, and are often troubled to toast a slice of bread quickly by holding it near the coals. If the bread is laid upon a support on the top of the stove, it dries hard before the surface is browned, impairing the sweetness, and requiring either very good teeth to masticate it, or to be moistened by hot water or milk. Or if a common fork be used, the fingers are burned, and the forks heated and loosened in the handle. To make the "holder," take two pieces of common wire about the size of coarse knitting needles, each 3 to $2\frac{1}{2}$ feet long. Twist them together to within about 5 inches of each end, bend the twisted part double, to bring the ends together, and then form the arms or supports as shown in the engraving. They can easily be sprung apart to receive a slice of bread, which can then be conven-

ently held in any desired position, without burning the fingers. A ring may be added to the end, by which to hang up the apparatus when not in use. It is an unpatented article, originated by one of the Editors of the *Agriculturist*, and is free to all.

Costume for the Garden, etc.

A "Farmer's wife" writes to the *American Agriculturist*: I have just been reading an article in the October number, page 307, wherein "Gardener," calls upon the ladies to devise a dress, in which they can visit the green-house to admire his beautiful plants, or work in the garden without destroying all with which they come in contact. Perhaps, he and others interested, would be pleased to know that such a dress has been devised, and is now worn by hundreds of ladies all through the Eastern and Western States. The "American Costume," which consist of a dress made in the ordinary way, except that the skirt is shortened so that it comes below the knees, with pants of the same material as the dress, forms a costume in which ladies can go up and down stairs with both hands full, work in the house or garden, or take morning walks when the dew is on the grass, without all the trouble and inconvenience attendant upon trailing robes. "After wearing the American Costume as a working dress, for over two years, I can say, that I find it very comfortable and convenient, and it has been pronounced by many sensible people as neat, modest, tasteful, and becoming."

About Starting Thirteen Million Fires.

An old adage, and a pretty true one, is, that "It takes a fool or a philosopher to build a fire well"—which, we suppose, means that the fool will blunder into the right way, the philosopher will reason himself into it, while others make bungling work of it. As nine-tenths of people belong to neither of the two classes, there is a deal of worry and bother. The ninety thousand families who receive this number of the *American Agriculturist* will need a fire started at least once a day, for the next five months, or in all over *thirteen million times!* How much time would be saved, if these fires could all be started so as to heat up the house, and get the breakfast and other things going, in half an hour, instead of the average time of an hour. (13½ million half hours equals 675,000 days of 10 hours each, or nearly 2,000 years. This multiplied by five in a family, amounts to 'considerable'.) How many colds would be prevented if the houses were warmed early for the children to wash and dress. So the subject of kindling fires is not so insignificant after all, even confining it to our own readers. Let us study the science of the matter a little, and try to increase the number of philosophers.

Heat results from the rapid union of the oxygen of the air with the carbon (coal) of wood or other combustible material. The more air, the more heat. We blow the fire with the natural bellows (lungs), or an artificial one, to drive more air upon it, and thus supply more oxygen. Stoves and chimneys are constructed to make the fire blow itself. Heated air expands, becomes lighter, rises up, and draws a current of fresh air after it. The longer or higher the stove pipe or chimney, the greater the upward draught. Open a hole in the side of a chimney, or stove, or stove-pipe, and part of the air drawn in comes through the hole instead of through the fire where it is wanted. Put the fire close to the front opening of the stove, or directly at the throat of the chimney, and it gets the full force of the in-rushing current of air, and oxidation or burning is intensified. Put the fire back in the stove, or low down on the hearth, and much of the current of air passes above it. The secret of starting a fire quickly is, to so arrange the kindling that it will receive the greatest possible draught at the very point where the first spark is applied; then arrange the fuel closely around it so as to allow it to spread rapidly. Throw a lot of kindlings loosely over a grate in the bottom of a coal

stove, and the draught is diffused all over the grate, and is not strong at any point. But cut the kindlings short, pack them closely in a little heap, and cover the rest of the grate with coal so as to partially stop the air current, except through the kindlings, and the latter will burn more intensely, and soon communicate fire to the rest. To secure this latter end, all fuel should be placed close together, with just space for the passage of air between the pieces. The finer the kindlings, the greater will be the surface exposed to the air, and the more rapid the burning. The best way is, to have a little fine or nut coal to put around the kindling. The small lumps will quickly heat through and take fire, and heat to the burning point the larger lumps placed in contact above and around them. A single handful of kindlings placed together and the draught of air concentrated at that point, is more effective in quickly starting a fire, than a large basketful thrown in at random. It is often well to close up all the grate with ashes underneath, except just under at the point where the match is applied, and then open more room for air as the fire spreads.

The above is the general principle, which may be applied in various ways. If the draught hole in the stove be in front, put the kindlings compactly close to the hole, and arrange the larger fuel upon and against them. In the wood fire-place, arrange the larger sticks to form a sort of pipe or narrow opening between them, for the kindlings. This will concentrate the air draught which is weak at first, directly upon the starting fire. The larger fuel placed above, in the line of the draught, will be rapidly ignited. The best chimney fire-places are those which have the throat placed high up, because the larger back surface thus exposed, acts as a radiator to throw heat out into the room. But to start the fire quickly, a blower (curved piece of sheet iron) is extended down from the throat to throw the draught through the fuel. The closer this iron fits to the throat and to the jams, the more effective will it be in directing all the air current through the fire.

There are several points relating to the best or cheapest fuel, modes of economizing it, best stoves and grates, best mode of conducting heat through buildings, best forms for fire-places and chimneys, smoking chimneys, etc., which may well occupy our attention, in the coming Winter numbers, especially in these times of high priced fuel.

What to Eat, and When to Eat What?

MR. EDITOR:—In your article on "Meals for a Week," in the November *Agriculturist*, there are some startling propositions—*chacun a son gout* finds pat application, and truly "there is no accounting for tastes." Yet it is a fact, that men of civilized nations have settled down into certain usages and proprieties, and consider infringements of these as incongruous with good taste. Custom among refined people and good livers, banishes pies, molasses-gingerbread, doughnuts, ordinarily cheese too, from the breakfast table, and "crust coffee" from anywhere but a sick room. "Sauce" is a much abused word—alone, it means nothing, except vulgarly, what we none of us like to take from any man. Compound condiments (not gravies) to eat upon meats or fish, are called sauces, as Worcester-shire sauce, caper sauce, etc. So stewed fruits in various forms are called sauces, as apple sauce, cranberry sauce; but what sauce is referred to by your correspondent, when he mentions "sauce and cheese, or broiled salt-fish" for breakfast, I do not know. Sauce, as a name for table vegetables is simply vulgar, if Webster does half authorize it. Your correspondent from Rahway has civilized notions; but the Andover man shows his utter disregard for all the proprieties of the table, when he says that his breakfasts for a week will, if meat-breakfasts are not desired, serve for dinners.

A few general principles in regard to meals seem to be established by convenience and natural propriety. In this country it is usual to have three meals a day—and these at morning, noon, and evening. For an early breakfast it is inconvenient to

have those kinds of food which require long preparation or cooking immediately before. Therefore roast, boiled, and baked meats, pastry and confectionery, and many kinds of vegetables find no place but broiled, fried, fricaseed, cold or hashed meats are appropriate, with sundry preparations of eggs, fried or stewed and sometimes baked potatoes, griddle cakes, etc. In hot weather, fruits, muskmelons, tomatoes, etc., are appropriately placed on the breakfast table. So also may stewed fruits (quite tart) be served. In the private family, propriety as well as convenience is outraged by a great variety of dishes which do not go well together. For example, apple-sauce which is excellent with pork-steak, is shocking with fried fish. KITCHENER.

How to Keep Beef.

In response to an inquiry for practical directions how to cure beef, so that it will keep until June, and yet not be too salt for the table, W. B. Dryer, Douglass Co., Ill., writes to the *American Agriculturist*: For every 100 pounds of beef, use seven pounds of salt, well rubbed on. Allow the beef to stand in the salt for twenty-four hours; take it from the vessel and pour off the drippings; then pack closely, and cover with brine, made as follows: For every 100 pounds of beef, 4 ounces of Saltpetre, 4 ounces of Bicarbonate Soda, 1 qt. Molasses.

E. A. Leonard, Defiance Co., Ohio, says: I allow the beef to cool sufficiently after killing, then cut it into convenient sized pieces for use, and pack it loosely into a barrel in which I have previously placed a quantity of weak brine. When the meat is all in, or the barrel full, see that the brine covers it. Let it stand two or three days, then take out the meat, throw away the brine, rinse out the barrel, and repack the meat snugly. Make a quantity of brine sufficient to cover the meat, and strong enough to hear up an egg. Add 2 ounces of saltpetre for every 100 pounds of meat, pour it on the meat, and it will keep until hot weather.

A subscriber in Greene Co., Ill., writes: To 8 gallons of rain water, add 2 pounds of brown sugar, 1 quart of molasses, 4 ounces of saltpetre, and enough of common salt to make brine sufficiently strong to float an egg. Rub the beef well with salt before placing it in the barrel. Then pour over it the prepared brine, and put on it a sufficient weight to keep the beef covered with the pickle.—Each of the above contributors says, that the method recommended has been tried by him several years, and the result was every way satisfactory. Where a considerable quantity of beef is to be cured, it might be well to try all the above ways on different parcels; we should like to hear which produces the best article next May or June.

Pickled Pork Equal to Fresh.

A lady contributor at Perry, Ill., sends the following directions to the *American Agriculturist*: "Let the meat cool thoroughly, cut it into pieces 4 to 6 inches wide, weigh them and pack as tight as possible in the barrel, salting very lightly. Cover the meat with brine made as strong as possible. Pour off a gallon of the brine and mix with it one tablespoonful of saltpetre for every hundred pounds of meat, and return it to the barrel. Let it stand one month, then take out the meat, let it drain twelve hours. Put the brine in an iron kettle, add one quart of molasses, or two lbs. of sugar, and boil until perfectly clear. When it is cold, return the meat to the barrel, and pour on the brine. Weight it down, and keep it covered close, and you will have the sweetest meat that you ever tasted."

Wire Clothes-Line.—Geo. E. Pomeroy, of Lenawee Co., Mich., says in reference to the use of galvanized wire for a clothes-line: "In the first days of telegraphing and the introduction of galvanized wire for telegraph use, I fancied it would make a good clothes-line. I used it and it worked well. In 1848 I moved to Michigan; I put up the

wire for a line, and it is now in use as good as the day it was put up: it never rusts or mildews, shrinks, or stretches. Tinned wire will not answer: it must be zinc-galvanized. The first cost is no more than hemp, and it will last always."

From the New England Farmer.

"West's Improved Pump."*

Editors of New England Farmer:—I can give Mr. Geo. C. Noyes the information that he wants. Perhaps in doing so I shall give a good many other persons some useful knowledge about pumps for farm use. If so, I shall be doing some good. In doing so, I may benefit the pump maker as well, but what of that? He is one who has done much for the benefit of others, by his powers of invention. So let us reciprocate.

West's improved pump is an anti-freezing pump. I have proved this four years. The only protection ever given is to open a small vent below the platform before freezing weather. This lets the water down from the spout in a minute or two after using the pump, but an extra stroke or two will fill the pipe again. In Summer this vent is plugged. In four years this pump has not required four cents' worth of repairs, though in daily use, often to the extent of many barrels a day, for the use of two houses and barn, neighbors and travelers. It is a good pump—the best I ever used. It does work easily—so easily that small children can always get water. It is not liable to get out of order. It is both a suction and force pump. I have a hose to screw on the muzzle, through which I can throw water wherever I please. There is also a place below the platform where a pipe can be attached, through which water can be forced any distance.

I have another of West's pumps in my kitchen, which draws water from a cistern twenty feet distant. This is like the one spoken of by you. The working part of the pipe will not freeze. The pipe below the pump requires protection. This, though in use continually, has never had a cent expended for repairs in four years, and it is but little more trouble to get water than it would be to draw it from a cask, it works so easily.

There may be other pumps equally good. I hope there are. The more the better. I don't know them; I do this, and give it this unequalled recommendation, for the benefit of others—of all farmers.

Near New York, Oct. 14, 1863. SOLON ROBINSON.

* This pump is manufactured by the inventor, Mr. J. D. West, 179 Broadway, New York City, who will doubtless send descriptive circulars to all applying for them.

Washing Machine Queries.

Letters without number are coming to hand, which we cannot find time to answer individually. We are weary of testing these machines, having tried a new one every few weeks for many years past. We have not, of course, tried every one of the thousand patented washing machines; but the only one which has stood the test with us for any length of time is the "Nonpareil." Doty's machine we have now under trial, and it promises well. The washing part is similar to that of the Nonpareil, while the operators seem to like the motion, which resembles the old-fashioned up and down washboard movement of the arms. Our first impression would be to call it one of the best, if not the best machine we have seen, but we have long since come to the conclusion to recommend no machine which has not been proved by long and thorough trial. Several years ago we thought the Metropolitan washing machine to be just the thing, and we still believe the principle—the combination of pestles on springs—to be better than anything else yet invented. But long trial developed the fact that working the pounder at arms' end, was too much like lifting a ladder, or working with the short arm of a lever, to adapt it to general use by the weaker sex. If strong men did all the washing, we would say get the Metropolitan. The balance wheel of the Nonpareil relieves the con-

stant strain upon the muscles. The only difficulty is that those habituated to the up and down motion in using a washboard, do not at once take to the crank movement. When the muscles become accustomed to it, the Nonpareil is much liked. The movement of Doty's machine will be a strong recommendation of it to that class who do not like to change their habits. Either of the machines named is a labor saver and a clothes saver, as compared with the washboard, and anything to save time on washing days, is certainly very desirable.

BOYS & GIRLS' COLUMNS.

To Our Young Readers.

Well, we have had pleasant times together for a year past! Although we could visit you but once a month, few, circles, if any, have had more agreeable and interesting entertainments than we have enjoyed together. We have laughed over the stories, puzzled our brains with the problems, learned curious and interesting facts in the Botany of common plants, and altogether have had much real pleasure and profit. But we are reminded by our subscription books, that some 60,000 of our nearly 90,000 subscribers, are now receiving the last visit which we have been invited to make. In the families of these subscribers there must of course be two or three hundred thousand girls and boys, or more, and we are glad to know, from hundreds of letters received, and from what parents tell us daily, that the *American Agriculturist* is the especial delight of the young people. That is just what we like to hear, and is just as it should be. This paper is for the Household—all of it. If we can interest, instruct, and improve the growing people, the boys and girls, our ambition will be greatly gratified. We want to see the next generation better than the present one, and to do all we possibly can to help in making it so.

Shall we say good-bye to any one of you? Certainly not. Our "school" keeps right on without vacations—the pupils say *Agriculturist* school hours are as pleasant as any "vacation."—The young folks do not have all the pleasure to themselves. What should we do without their company? How blank and desolate would our own home be, if the group of little ones were not there to greet us on our return from each day's weary labors. How lonely the rooms would be if we found not the sleepers there as we passed through them, the last thing before retiring at night, as is our custom, to see that all are "tucked up" snugly, and resting quietly. How dull the waking hours if we missed the taps at the door and the pleasant "Good morning papa." Cheerless would be the breakfast circle if there were no occupants for the little and larger chairs around to the right and left.

Perhaps we could endure it if our household was made up wholly of grown people, but we are glad it is not—we almost wish the little ones would not grow large. Our greatest desire is that they shall grow up wise and good. The same feelings that go out to our own little ones, and to the larger circle that greet us on Sunday afternoons, are in a measure extended to that still greater company of children and youth who make up the *Agriculturist* family. They are scattered, it is true, over the broad expanse from the Atlantic to the Pacific, but when we sit down to prepare this department of the paper, we in imagination gather them all around us. We shall love to continue the "Boys' and Girls' columns," and to make them even much more interesting and profitable. That you may here gain instruction as well as amusement is our anxious desire. We shall therefore be happy to meet you all during 1864—not one can be spared. Come on by tens, by twenties and by hundreds; there is room enough, and supplies of good things are plentiful. Invite your playmates to join the circle. All of you can get one, or more. There are many premiums you can earn. We have sent out a large number of these to boys and girls, some of them every year, and there is always a peculiar pleasure in doing so. Can we not double the number this year? Will you bring at least one more?

About the Origin of Words.

Where do all the words come from? Men do not agree as to how language was made at first. By many, however, it is supposed that man received the gift of speech at his creation. However this may be, we know that new words are being added to every language, as men have new thoughts and make new discoveries requiring new terms to express them. Thus the word "telegram" has been invented within a few years as the name of a message sent by the telegraph. It is often very interesting to trace out the derivation of words; sometimes quite a history is connected with them. Thus the term *dunce* so often used, is said to have come from the following cir-

cumstance: A Franciscan monk, named Duns Scotus, had many followers, who used often to quote his writings in defence of their doctrines, and as these doctrines became unpopular, the term Dunsman or Duns was used as a term of contempt for those who advocated them. From this it came to be applied to any person whose notions were considered unreasonable, and with a little alteration in spelling we now use it to designate a stupid person. Our word "tariff," meaning tax or duty paid on imported goods, comes from Tarifa, the name of a Moorish fortress on a promontory at the southern point of Spain, extending into the strait of Gibraltar. At this point the Moors used to watch all vessels passing through the strait, and require their owners to pay a tax for the merchandise they carried. "Hurrah," is from the word Hurrag, which was used in old times as a battle cry, by some of the warlike nations of Europe. It signified "To Paradise." They believed that every man who died in battle for his country, went immediately to heaven. A curious account is given of the origin of the word "Teetotal," so commonly used to express entire abstinence from intoxicating drinks. It is said that a Lancashire laborer in his first public speech on temperance, was much embarrassed, and repeatedly stammered at the word total, making it t-t-t-total, and the amused audience afterward frequently repeated it, and others took it up until it became a fixed word in the language. Many more examples might be given. Our young readers will find instructive amusement in studying the derivation of most words. How many of them can tell the origin and meaning of the name of this journal—the *American Agriculturist*.

New Puzzles to be Answered.

No. 59. Puzzling Sentence.

—This has appeared in print before, but it will probably be new to many of our young readers. It was constructed in commemoration of a great historical event. Those who study it out, will be pretty sure to remember the occurrences and their date.

It will be interesting to read the whole history of which this puzzle forms a part.

No. 60. The Wheel Puzzle.—As every body knows, a small wheel must turn around more times than a large one, in rolling over equal distances. Now when you examine a wagon wheel, you notice that it is composed of two circles or wheels, the tire and felloe or outer circumference, and the hub or smaller wheel at the center. Why, in rolling any number of miles, does this smaller wheel revolve no oftener than the outer or larger one?

No. 61. Illustrated Rebus.—A rule for successful life.

Answers to Problems and Puzzles.

The following are solutions of the puzzles, etc., in the October number, page 345. No. 55.—Sentence in Cypher. The key to this is to take for the first, third and fifth letter of every word, the next letter above it, as a for b, m for n, etc. For the second, fourth, and sixth letter, take the third letter above in the alphabet, as m for p, u for x:

Ukf krnuom ddmofg ukf bptufbq bjsldxmwvjuv jv gys ukf gdsq hdsqf bqe lrvvfkpc jdvovgqnh ukf nlnvnh grmt. Jv drwt pamb paf ermobu b zbnu. Qofth nhmo bom zrnu gujhogt bexu jv bqe bvl ukfp ur udth jv. Ukfb xhmo nllh jv bqc ukbql zrv.—No. 56. Puzzle Picture.—The boy is making mellow D (melody).—No. 57. Illustrated Rebus.—Four chair I T covers a multitude of sins = "For Charity covers a multitude of sins."

—No. 58. Miscellaneous Questions.—A step farther, (step-father); Room for improvement; the Alphabet.—The following have sent in correct answers up to Nov. 13th, the numbers indicate the problems, etc., answered by each. R. Van Namee, 55; "A. N. H. E.," 58; Estis, 57; H. F. Boynton, 55, 57; "E. E. K.," 55, 57, 58; J. N. Miller, 56; Emily L. Webb, 57; Charles Munger and Orra Bruce, 57, 58; T. S. Peck, 57; Daniel Gilbert, 57, 58; O. Coombs, 51; J. H. Ransom, 53; W. Johnson, 53.

"ASTONISHMENT."—FROM A PAINTING BY W. HUNT.

Engraved for the American Agriculturist.

The Boy in the Picture—Self Control.

Very much astonished indeed this lad must be. His looks show that his senses seem to have escaped from his eyes and open mouth, even faster than the milk is pouring from the pan he is carrying, but which he appears to have entirely forgotten. What he is gazing at, we can not even guess—perhaps at a white cow, which in the twilight he fancies to be a ghost; or as a friend at our elbow suggests, perhaps he is "taken all aback by seeing a silver half dollar," which, in these times would be a novel sight. It is very plain that he has never learned to be master of himself. He would certainly make a poor soldier; the first shell that came whizzing near him would make him forget his musket, his companions, and his duty, and he would be of no more use than a wooden image. But he may not be much to blame for all that. It is no easy matter to learn to control all one's powers. It takes years of practice to know how to manage a steam engine, but what is that compared with the wonderful machine—the body with a mind in it—that every boy and girl possesses? The lad in the picture appears like a neglected boy, kept by some unthinking employer just to do chores, and with no thought or care for him only to keep him at work. There are such men, but it is of little use to say any thing about them here, for they are not of the sort that take the *American Agriculturist* or any other good paper for themselves and their girls and boys to read.—It is the testimony of the Wise Man that "He that ruleth his own spirit is greater than he that taketh a city," and it will be found that no one is fitted to rule others until he has gained some mastery over his own powers. Strive to train your eyes,

ears, tongue, hands, feet, all the faculties, to act rightly and at the right time, and it will save not only a good deal of "spilt milk" but of spoiled life.—The most difficult thing to control is the temper. An aged friend of ours, who is noted for his calmness, says he commenced when a little boy to always count seventy-two before speaking, when he began to feel angry about anything. *

"A Merry Christmas."

It will soon be here. Already the little folks are counting the weeks and days before Dec. 25th. Some boys are dreaming of new skates, sleds, knives, or books; the girls, of dolls, play houses, puzzles, and other gifts of Santa Claus. Christmas should be the happiest holiday of the year. Most other holidays are in commemoration of events which pertain to the particular history of the nation in which they are celebrated. Thus we, as a people, have our Fourth of July and 22d of February; in England, the Fifth of November is celebrated; in Germany, the 18th of October. (It will be interesting for you to learn from history why these days are specially regarded in those countries.) Christmas, however, is or should be a holiday for all nations. It is in remembrance of the *Great Gift* to mankind. In all Christian nations, it is remembered with rejoicing. The exact time of the birth of Christ is not determined, but, as you know, all have agreed to keep up the 25th of December, to bring to mind that event. The word Christmas means a *mass* or special worship to Christ. It came to be called "Merry" from the revels and sports which were instituted in England, at Christmas times, extending formerly from Dec. 25th to Candlemas (Feb. 2d). In the houses of the nobles

a "lord of misrule" was appointed whose business it is said by an old writer, was "to make the rarest pastimes, to delight the beholder." An immense fire was built in the largest room in the old castles, on which a great log, called the "Yule log," was kept burning until Candlemas. The laborers were all invited into the castle, to feast, and dance, play games, and engage in every kind of amusement. These scenes must often have been tumultuous, as barrels of ale and great bowls of punch were freely given out to the revelers. Although such scenes are not now enacted, Christmas is nowhere observed with greater spirit than in England. In Germany and the north of Europe, this day is often called the "children's festival," and the Christmas tree is introduced on the preceding evening. A very interesting custom on this occasion is observed in some places. After the presents from the Christmas tree have been distributed, the mother takes opportunity to say privately to the daughters, and the father to the sons, what has been observed most praiseworthy and what most faulty in their conduct. In other places, the youngest child on behalf of the others, makes a little speech to the parents, expressing their love and gratitude; the writer once witnessed this performance where the occasion was kept in true German style. We are pleased to notice that in late years the observance of Christmas is becoming more general in the United States. Many families have the Christmas tree, bearing its beautiful fruit of presents for old and young, though in most places the good old-fashioned plan still prevails of hanging the stockings in the chimney corner for Santa Claus to fill. From our hearts we wish you all a Merry Christmas this year, with stockings full of presents to help make it so; but all will be pretty sure to have it, who take care to keep their stockings filled with good children's feet, until that time.

Amusing Remarks of Children.

A very talkative little girl used often to annoy her mother by making remarks about the visitors that came to the house. On one occasion a gentleman was expected whose nose had been accidentally flattened nearly to his face. The mother cautioned her child particularly to say nothing about this feature: imagine her consternation when the little one exclaimed, "Ma, you told me to say nothing about Mr. Smith's nose, why he hasn't got any!"—This recalls an anecdote of a little girl whose teacher often had occasion to reprimand her. One day she gave the child an unusually long and sharp talk for some grave offence, and from the steady attention of the latter, supposed she was making a strong impression on her, when suddenly the little girl exclaimed, "Why Miss Jones, when you talk, your upper jaw don't move a bit."

A Thick Fog—A Quizzer Rebuked.

A talkative individual encountered a quiet old gentleman on the ferry boat one morning, and vainly endeavored to draw him into conversation—evidently with a desire to make sport of him, but without much success. At length the talker remarked, "I suppose you consider Down East a right smart place; but I guess it would puzzle them to get up as thick a fog as we have here this morning." "Well," said the old man, "I don't know about that. I hired one of your York chaps to work for me last Summer, and one rather foggy mornin' I sent him down into the meadow to lay a few courses of shingle on a new barn I was finishin' off. At dinner-time the fellow came up, and sez he, 'That's a long barn of yours.' Sez I, 'Not very long.' 'Well,' sez he, 'I've been to work all this forenoon, and haven't got one course laid yet.' 'Well,' sez I, 'You're a lazy fellow, that's all I've got to say.' And so after dinner I went down to see what he'd been about, and don't you believe, he had shingled more than a hundred feet *right on to the fog!*' "Answer a fool according to his folly said the Wise Man."

Reading One's own Obituary.

An eastern journal had a subscriber who had not paid up in several years, though he often promised to "call and settle." Finally after a sharp dun he said, "If I don't come and pay up to-morrow, you may be sure I am dead." The next day came, but no money. On the following morning the subscriber was horrified at reading in the journal a notice of his own death, giving a sketch of his life, and recounting many good qualities he possessed, but stating that one of his failings was his neglect to pay the printer. Seizing his hat he posted to the office and exclaimed, "What does this mean?" "Why" replied the editor, "you told me I might consider you dead unless that bill was settled yesterday, and knowing you to be a man of your word, I wrote accordingly." "Oh! ah! yes, I see," said the subscriber, "here's your money; and now, if you please, contradict the report in your next paper." "That's not necessary," replied the editor, "the article was printed only in the copy of the paper sent to you!" He took the hint, and ever after paid the printer promptly.

The habit of observation, and of scientific study cultivated in children where a Barometer is used, is important.

H—The Aquarius.—This is an excellent little portable force-pump, useful in many ways. One can take this instrument in his hand with a pail of water, and throw a considerable stream to any point where a fire may be breaking out, and do more to quench it, than he could with a dozen pailfuls dashed on, even if the fire could be reached. We have thrown water from the ground up against the third story windows of a house. The Aquarius is very useful for watering gardens, for washing windows, carriages, etc., etc. It is provided with rubber suction pipe, to draw water from a pail, tub or bucket, and an ejection pipe having both a nozzle for throwing a stream, and a rose or sprinkler. It has also an air chamber for giving a constant stream. It is a handy instrument, for every household, aside from its use as a fire engine with which incipient fires have been stopped.

I—J—Melodeons.—None need be told of the pleasure given by a good Melodeon in a household, or of its utility in the Week Day and Sabbath School Room, and the Church. "Music hath charms to soothe even a savage breast," and we hesitate not to say that a benign influence is exerted upon every house and school room where a Melodeon or other good musical instrument is found. We offer two sizes in our list above, and those of a different price may be selected for a proportionate number of subscribers. (For sizes, style, prices, etc., send a stamp to George A. Prince & Co., Buffalo, N. Y., and get one of their illustrated descriptive Catalogues, which will be sent free). We have used one of these Melodeons during four years past, and it continues to give the highest satisfaction. It has not been tuned or otherwise repaired in all that time. The premium instruments will be shipped direct from the manufacturers at Buffalo, ready boxed. They can go by railroad, steamboat, express or otherwise, as desired by the recipient. It is easy for Churches, and both Week Day and Sunday Schools to unite their efforts and secure a good melodeon.

—Many have done so already.

K—Q—Seven Volumes of the Agriculturist.—Here is a whole *Agricultural, Horticultural, and Household Library*, embracing also a large amount of interesting reading for Children and Youth, and thousands of instructive and pleasing engravings. Each volume contains more printed matter than half a dozen dollar books of the usual size. There are in each volume from one to two thousand articles and condensed items, among which every reader will find something useful to himself and family. We send them post-paid (as in the above table) in new clean numbers, printed from stereotype plates as needed. The last number of each volume contains an index to the whole volume. (Any person preferring them bound, can receive them in this form, neatly done, at 65 cents extra per volume, for binding and extra postage—or at a cost of only 25 cents per volume if called for, or sent by express, or otherwise, so as not to be pre-paid. Let every one selecting this premium be sure to name what volumes are desired, or how many of each, as duplicates of any number can be chosen if preferred.—We can only supply from volume 16 to volume 23 inclusive.

R—Best File for the Agriculturist.—Jacob's Portfolio file, made just to fit the *Agriculturist*, with the name of the paper gilded on, is exceedingly convenient. It is a neatly embossed or stamped cover, made so that each successive number of the paper can be inserted in a minute, when it is strongly held in. The numbers thus fastened together are as convenient as a bound book. When one volume is completed, it can be removed and stitched together, and the numbers of a new volume be inserted. A single cover will answer for a dozen or twenty successive years. It is without doubt the most perfect paper file made. Sent post-paid.

S—Water Color Paints.—Those offered (Osborne & Hodgkinson's) are the best of American Manufacture, and though not so fine for artist's work, as some of the imported (which now sell at six times the price), they answer very well for common sketching, particularly by children and beginners. They are especially useful to children, as their use tends to develop a taste for form and color, and skill in the use of the pencil. Sent post-paid, in neat mahogany case—24 small cakes of assorted colors, with brushes, etc.

T—U—Premium Plows.—The two named in the table above (*Cylinder and Eagle No. 24*) are two of the best farm plows in use, and will doubtless give ample satisfaction to any one securing them as premiums. We have not space for a particular description. The Eagle Plow is well-known. The working of the Cylinder Plow, and other items concerning it are described on page 136 of Volume XX, (May 1881).

V—W—Hay and Straw Cutters—Steel-toothed Cultivators.—These implements are of first importance to all farmers, some of whom may find it most convenient to secure them through our premium list. We send the best implements we know of at the prices named.

The Markets.

AMERICAN AGRICULTURIST OFFICE,
New-York, Thursday Morning, Nov. 19, 1883.

The tables below, carefully prepared specially for the *American Agriculturist*, from original and official sources, present a very comprehensive and clear view of the transactions in breadstuffs, during the past month and year, and a comparison with similar periods last year. A study of the tables will afford much general information.... Prices of most agricultural products have advanced, as shown in the tables of current rates. This has mainly resulted from the advance in gold, as was fully detailed on page 328, November *Agriculturist*. The Breadstuff markets are at present in a very unhealthy condition, owing to the rage for speculation, and most of the reported sales are from one to another of this class. Buyers for the home trade and for shipment hold off, expecting a collapse which will be produced by military suc-

cesses followed by a fall in gold, or by a tighter money market.... Bale Hay has been very scarce and in lively request at higher rates.... Hops have been more sought after and quite firm.... Seeds, Hemp, and Tobacco, have been in less request, but without important changes in prices.... Wool has been in very brisk request, chiefly for manufacturing purposes, and heavy sales of both domestic and foreign have been effected, (including an extensive catalogue of California and foreign Wools at auction, Nov. 12,) at decidedly firmer prices, the market closing with less animation, owing to the extreme firmness of holders. Stocks have been much reduced, and the finer grades are now becoming scarce.... In most agricultural products, transactions have been moderate. The Price table shows present prices, and changes since our last quotations.

The N. Y. Live Stock Markets during the past 5 weeks have been largely supplied, the average weekly receipts being 6,225 beef cattle; 16,888 sheep, and 43,000 live hogs. The short winter forage hastens the marketing of animals. The demand is good, and even under the large receipts, prices are well maintained, the present rates being: for cattle, 11c. 7½ lb. estimated dressed weight for the best, and down to 6c for scrawls—average of all sales 8½c. Good full grown Sheep bring 5½c @ 5½c. 7 lb. live weight; Lambs 6 @ 7c. Good corn-fed hogs, 6 @ 6½c. 7 lb. live weight; still-fed, 5½ @ 5½c.

BUCKEYE MOWER

AND REAPER.

For the Season of 1864.

The scarcity and high prices of labor during the past season, caused a demand for Harvesting Machinery, much greater than manufacturers could supply. The fresh calls of the Government for troops will take many thousand more laborers from the country before the next harvest, and the farmer will have to rely almost entirely upon machinery in gathering his hay and grain crop.

Farmers who were disappointed in procuring BUCKEYES, can avoid a similar disappointment by purchasing Machines this Winter.

We are now prepared to take orders for Machines of the various sizes.

Circulars with terms and prices forwarded by mail.

ADRIANCE, PLATT & CO.,
Manufacturers and Proprietors.

Manufactory, Poughkeepsie,
Warehouse 165 Greenwich-St., New-York.

THE EUREKA FEED CUTTER.

A Cutter adapted to the wants of Farmers.

FIRST RATE FOR
CORN STALKS,

HAY and STRAW.

This machine has important improvements. It CRUSHES and CUTS the heaviest corn stalks, and hay and straw with great rapidity, by either hand or horse power. It has four cylindrical knives, ground on the inside; they cut with the SHEAR CUT, and can be EASILY ground and kept in complete cutting order by ordinary farm help. It is well made, easily operated, simple, durable, and effective. Hundreds are in actual operation to the perfect satisfaction of the purchasers. Orders solicited—promptly attended to. Send for a circular, furnished FREE. Manufactured only by

H. K. PARSONS, AGENT,
Novelty Works, HARRISBURG, PA.

BROWN'S BRONCHIAL TROCHES FOR COUGHS AND COLDS.

A NEGLECTED COUGH, COLD, AN IRRITATED OR SORE THROAT if allowed to progress, results in serious Pulmonary Bronchial and Asthmatic Diseases, often times incurable. BROWN'S BRONCHIAL TROCHES reach directly the affected parts, and give almost immediate relief. For BRONCHITIS, ASTHMA, CATARRH, AND CONSUMPTIVE COUGHS the Troches are useful. PUBLIC SPEAKERS and SINGERS should have the Troches to clear and strengthen the voice. MILITARY OFFICERS and SOLDIERS who overtax the voice, and are exposed to sudden changes should use them. OBTAIN only the genuine. "Brown's Bronchial Troches" having proved their efficacy by a test of many years, are highly recommended and prescribed by Physicians and Surgeons in the Army, and have received testimonials from many eminent men.

Sold by all Druggists and Dealers in Medicine in the United States and most Foreign countries at 25 cts. per box.

Steel Composition Bells.

THE AMERICAN BELL COMPANY.

(Office No. 39 Liberty-street, New-York.)

Are the only manufacturers of this description of Bell either in this country or in Europe—the combining of certain metals, and the process of manufacturing the same being the discovery of the President of the Company. These Bells we can commend with great confidence to the public, for their cheapness and quality of tone. We furnish a 500 lb. bell with all the necessary appointments—including Harrison's patented Self-acting Rotary, for \$25, and one of 1000 lbs. with like appointments, for \$250. The price for the Bells being 20c. per pound, and that of the hangings of the first, \$25, and those of the latter \$42. Our circulars, containing full details, will be forwarded free of charge to all parties desiring the same.

of the first, \$25, and those of the latter \$42. Our circulars, containing full details, will be forwarded free of charge to all parties desiring the same.

Amalgam Bells.

At prices within the reach of every Church, School, Cemetery, Factory, or Farm in the land. Their use throughout the United States and Canada for the past six years has proven them to combine most valuable qualities, among which are TONE, STRENGTH, SONOROUSNESS, and DURABILITY OF VIBRATION, unequalled by any other manufacture. Sizes from 50 to 5000 lbs., costing two-thirds less than other metal, or 15 cents per pound at which price, we warrant them twelve months. Old bell metal taken in exchange, or bought for cash. Send for a Circular to the Manufacturer.

FOR EVERY FAMILY.

DOTY'S NEW-YORK CLOTHES WASHER.

Patented July 21st, 1863, by WM. M. DOTY, New-York City.
Has Proved itself to be the
Best Washing Machine

For General Family Use.

It combines the three great essentials, viz:

**Rapidity of Washing, Ease of
Operation, and Cheapness.**

To a greater degree than any other Washing Machine ever invented.

It WASHES either a large or small bulk at a time without danger of injury. It is COVERED while in operation, to keep the suds from cooling.

It is easily worked while **Sitting Down.**

It is so EASY OF OPERATION, that mere children can easily do out large washings with it, the clothes requiring NEITHER RUBBING NOR BOILING. It RINSES, as well as washes.

It is so SIMPLE that the most ignorant readily understand it; and it REQUIRES NO REGULATING of any kind. It is ready any moment to go to work, or to stop, and takes but little room.

It HAS BUT LITTLE MACHINERY; none in the Water, liable to rust or swell; and none at all but what is DURABLE.

It COSTS so LITTLE that none need do without its great aid, and proves a GOOD INVESTMENT AS A CLOTHES SAVER ALONE.

It has the **Highest Testimonials**: Read the following specimen:

15 LAIGHT ST., N. Y., Oct. 10, 1863.

MR. WM. M. DOTY.

Sir,—From my experience in the use of Washing Machines, I am satisfied that your "NEW-YORK CLOTHES WASHER" combines all the requisites of a good washer, and is the BEST AND CHEAPEST hand washing machine I have ever seen. It is truly

A GREAT LABOR SAVER,

and its simplicity, durability, cheapness and ease of operation make it ESPECIALLY ADAPTED TO FAMILY USE. The superior and speedy manner in which it does the work without injury to the fabric, must be satisfactory to all who use it, and I cheerfully recommend it to public favor and patronage.

A. HOLLAND,

Author and Publisher Laundry Manual.

We, the undersigned, having thoroughly tested "Doty's New York Clothes Washer," fully endorse the above recommendation, by Mr. A. Holland.

SOLON ROBINSON, Agricultural Editor N. Y. Tribune.
JAMES BROWN, Brown Brothers & Co., 59 Wall-st.

In short, it is JUST WHAT IS NEEDED IN EVERY FAMILY, and what it has taken THOUSANDS OF YEARS and OVER A THOUSAND INVENTIONS to bring forth. Do not be without one in your Family, on any account.

Washing with the WASHBOARD is too severe labor for most women. Indeed, it is

Killing Them by Thousands!

Besides wearing out millions of dollar's worth of clothes.

SAVE THEM!!!

Both the Women and the clothes, by procuring

"Doty's New York Clothes Washer."

Price \$10. Weight about 55 lbs. Agents wanted everywhere. Send for a Circular.

WM. M. DOTY, 493 Broadway, New-York.

ADAMS PRESS CO., 31 Park Row, N. Y.

Mode of applying JOHNS & CROSLY'S

GUTTA PERCHA CEMENT ROOFING.

This Roofing is Fire and Water Proof, and can be applied by any ordinary laborer. It costs only about one-third as much as tin, and is more durable.

GUTTA PERCHA CEMENT PAINT applied to leaky roofs of all kinds, will render them perfectly water-tight. It is put up *ready prepared for use* and for shipment to all parts of the country. This Paint is particularly adapted for painting Out-houses, Barns, Fences, &c., &c., and will effectually prevent wood from decaying.

These materials have been tested on more than twelve thousand roofs during the past six years, and we can give abundant proof of all we claim for them. Full descriptive circulars and any required information furnished by the
JOHNS & CROSLY MANUFACTURING CO.
78 William-st., cor. Liberty, New-York.

The NONPAREIL WASHING MACHINE

Is the only entirely reliable machine in use.

It has been before the public nearly three years, and has not in any instance failed to give satisfaction.

It saves two-thirds the labor and time required in hand washing.

It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it.

It will not get out of order.

It is recommended by Mr. Judd, the proprietor of this Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20.

Send for free Circular to

OAKLEY & KEATING, 73 South-st., New-York.

Mason & Hamlin's CABINET ORGANS.

Essentially different from, and a great improvement upon Harmoniums, Melodeons and all similar instruments. The manufacturers would hesitate to claim this pre-eminence for their instruments, however well satisfied they might be of the fact, were it not endorsed by the WRITTEN TESTIMONY OF A VERY LARGE PORTION OF THE MOST EMINENT MUSICIANS IN THE COUNTRY. More than one hundred and fifty of the most eminent organists and artists in the country have given their written testimony to the great excellence of the cabinet organs, and that they surpass all instruments of their class.

The most eminent composers of church music in the country, as LOWELL MASON, WM. B. BRADBURY, GEORGE F. ROOT, THOMAS HASTINGS and others; the most eminent pianists in the country, as GOTTSCHALK, WILLIAM MASON, MILLS, WOLLENHAUPT, SANDERSON, STRAKOSCH, and others; the most eminent organists in the country, as MORGAN, ZUNDEL, WILLCOX, TUCKERMAN, CUTLER, and a host of others have all given the most emphatic testimony to the great superiority of these instruments to all others of their class, which testimony may be found in full in our illustrated catalogues.

The CABINET ORGAN is to private houses, Sabbath Schools, and Lecture Rooms, and smaller churches, what the large pipe organ is to larger churches and halls. It occupies little room, is elegant as a piece of furniture, easily transported, and not liable to get out of order.

The AUTOMATIC BELLOWS SWELL, patented October 1862, and used only in these instruments, enables the bellows (as testified by the *Musical Review*) "to approach even, the human bellows, the lungs in capacity for expression."

STYLES AND PRICES.

No. 10. CABINET ORGAN.—Our largest size; for churches, halls and private use. It has twelve stops, drawing six complete sets of reeds; two manuals of five octaves each, and a pedal base of two full octaves. Price in solid oak or black walnut case \$500; in Rosewood \$600.

No. 11. CABINET ORGAN.—Has eight stops, four complete sets of reeds, two manuals, of five octaves each, and the Automatic Swell. Rosewood case, \$450.

No. 12. CABINET ORGAN.—The same as No. 11, except that the case is of oak or black walnut; \$380.

No. 14. CABINET ORGAN.—Has six stops, three sets of reeds, one manual of five octaves with Automatic Swell. Oak or black walnut case \$360.

No. 23. CABINET ORGAN.—Has knee stop, two sets of reeds, one manual of five octaves, compass, with Automatic Swell. Black walnut case, paneled and ornamented with carvings, \$170.

No. 22. CABINET ORGAN is the same as No. 23, except that the case is of rosewood, \$170.

No. 21. CABINET ORGAN is the same as No. 22, except that the case is of solid black walnut or oak, \$140.

No. 20. CABINET ORGAN has two sets of reeds knee stop, Automatic Swell, one manual of four octaves compass. Rosewood case, \$140.

No. 19. CABINET ORGAN is the same as No. 20 except that the case is of black walnut or oak, \$115.

No. 18. CABINET ORGAN has one manual of five octaves, with one set of reeds, and Automatic Swell. Rosewood case \$125.

No. 17. CABINET ORGAN is the same as No. 18, except that the case is of black walnut or oak, \$100.

No. 16. CABINET ORGAN has one manual of four octaves, one set of reeds with Automatic Swell. Rosewood case, \$110.

No. 15. CABINET ORGAN is the same as No. 16, except that the case is of black walnut or oak, \$85.

All the rosewood cases are highly polished and elegantly finished. The black walnut and oak cases are smooth oil finished, but not polished.

Send for an Illustrated Catalogue which will be sent free to any address. Warerooms No. 7 Mercer street, New-York, No. 274 Washington street, Boston. Address

MASON BROTHERS, New-York, or
MASON & HAMLIN, Boston.

Along the road you cantering go,
Five or six miles an hour or so;
You've only to rise and sit as you ride,
The horse by his bridle you easily guide.

A Patent Horse, to carry his master,
Needs no spur to make him go faster;
Runs along cheerily as soon as you stride him,
Ready to go wherever you guide him.

FOR EVERY BOY AND GIRL. SOMETHING NEW.

A Wonderful **CANTERING HORSE**, which goes by the weight of the rider, runs with the greatest ease, and is guided as readily by the bridle as the gentlest Horse. The propelling and steering apparatus is new, simple, and very efficient. It is **Strongly Made and is very Durable, and Cheap.**—Just the thing for the Holidays.

Call and see the **New Horse**, or send for it, or send for a book of Illustrations and descriptions, which will be furnished by enclosing stamp.

N. B.—This Horse can be run on any hard road, and is strong enough to carry a man of **300 pounds** weight. It is a capital thing for **INVALIDS**, and for **CRIPPLES**. It has side-saddles for **GIRLS**, who can ride this horse, as well as **BOYS**.

STEPHEN W. SMITH, Proprietor,
498 Broadway, New-York. (Opposite St. Nicholas Hotel.)

SELF-ADJUSTING AND ADJUSTABLE!

The only Wringer with the Patent
Cog Wheel Regulator,

which **POSITIVELY** prevents the rolls from
BREAKING, OR TWISTING ON THE SHAFT.

It was pronounced superior to all others at the World's Fair at London, 1862. It took the **FIRST PREMIUM** at the great Fair of the **AMERICAN INSTITUTE**, New-York City, 1863, where the Judges were practical mechanics, and appreciated **COG WHEELS**.

It took the **FIRST PREMIUM** at the
NEW-YORK STATE FAIR.....1862 and 1863.
VERMONT STATE FAIR.....1863.
PENNSYLVANIA STATE FAIR.....1863.
IOWA STATE FAIR.....1863.
ILLINOIS STATE FAIR.....1863.
MICHIGAN STATE FAIR.....1863.

And County Fairs without number.
ORANGE JUDG, of the American Agriculturist, says of the
UNIVERSAL CLOTHES WRINGER,

"We think the machine much more than **PAYS FOR ITS SELF EVERY YEAR** in the saving of garments! There are several kinds, nearly alike in general construction, but we consider it important that the Wringer be fitted with **Cogs**, otherwise a mass of garments may clog the rollers, and the rollers upon the crank-shaft slip and tear the clothes, or the rubber break loose from the shaft. Our own is one of the best made, and it is as **GOOD AS NEW** after nearly **FOUR YEARS' CONSTANT USE.**"

We have seven sizes, from \$5.50 to \$30. The ordinary family sizes are No. 1, \$10, and No. 2, \$7. These have
COG-WHEELS,
and are **WARRANTED** in every particular.
On receipt of the price, from places where no one is selling, we will send the **U. C. W., FREE OF EXPENSE.** What we especially want is a good
CANVASSER

In every town. We offer liberal inducements and guarantee the exclusive sale.
R. C. BROWNING,
317 Broadway, New-York.

GREAT DIS-
COVERY!

USEFUL and VALUABLE DISCOVERY!

HILTON'S INSOLUBLE CEMENT!

Is of more general practical utility than any invention now before the public. It has been thoroughly tested during the last two years by practical men, and pronounced by all to
Be Superior to any
Adhesive Preparation known.

Hilton's Insoluble Cement
Is a new thing, and the result of years of study; its combination is on
SCIENTIFIC PRINCIPLES,
And under no circumstances or change of temperature, will it become corrupt or emit any offensive smell.

Boot and Shoe Manufacturers, using Machines, will find it the best article known for Cementing the Channels, as it works without delay, is not affected by any change of temperature.

Jewelers will find it sufficiently adhesive for their use, as has been proved.

Families. It is especially adapted to **Leather**, and we claim as an especial merit, that it sticks patches and Linings to Boots and Shoes sufficiently strong without stitching.

IT IS THE ONLY
LIQUID CEMENT
Extant, that is a sure thing for mending
Furniture, Crockery, Toys, Bone, Ivory, and articles of Household use.

REMEMBER
Hilton's Insoluble Cement
Is in liquid form and as easily applied as paste.

Hilton's Insoluble Cement
Is insoluble in water or oil.
Hilton's Insoluble Cement
Adheres oily substances.

Supplied in Family or Manufacturers' Packages from 2 ounces to 100 lbs.

The Best Reading Books in the English Language.

JUST PUBLISHED. HILLARD'S READERS. NEW SERIES.

HILLARD'S SIXTH READER.
HILLARD'S FIFTH READER.
HILLARD'S INTERMEDIATE READER, ILLUSTRATED.
HILLARD'S FOURTH READER, ILLUSTRATED.
HILLARD'S THIRD (PRIMARY) READER, ILLUSTRATED.
HILLARD'S SECOND (PRIMARY) READER, ILLUSTRATED.
HILLARD'S FIRST (PRIMARY) READER, ILLUSTRATED.

In the Fourth, Intermediate, Fifth, and Sixth Readers, a FEW of the MOST APPROVED selections in the compiler's former series are reproduced, but the selections for the most part are derived from other sources, and the examination of English literature has been very extensive to find a variety of pieces of intrinsic worth and permanent merit.

Great care has been taken that the different numbers of the NEW SERIES should be CAREFULLY GRADUATED to the capacity of the classes for which they are designed.

School Officers and Teachers are invited to address the Publishers.

Copies of the books will be furnished to teachers and school officers only, for examination, or they will be sent by mail on receipt of the postage, which is for the Sixth, 24 cts.; Fifth, 20 cts.; Fourth, 16 cts.; Third Primary, 12 cts.; Second Primary, 8 cts.; and First Primary, 8 cts.

The publication of the Old Series will be continued as heretofore.

BREWER & TILESTON,
131 Washington Street, Boston, Mass.

Choirs, Conventions, and Singing Schools, ARE USING

The Best Music Book of the Season "THE HARP OF JUDAH"

Which, though published but a few weeks, has attained
A POPULARITY UNEQUALLED,

By any similar work, and is meeting with
A Demand Unprecedented ;

Insuring within three months
A SALE OF FIFTY THOUSAND COPIES.

Several Conventions have used it with entire satisfaction—twelve more Conventions will use it this month—and a large number are making arrangements for the coming season. Choirs find no book equal to it for practice—and certainly a book so available for Conventions and Choirs cannot be otherwise than the book for Singing Schools. Specimen pages sent free. Price of "The Harp of Judah," \$1 per copy; \$9 per doz. Sold by all Music Dealers and Booksellers. OLIVER DITSON & Co., Publishers, Boston, Mass.

LIEBIG'S GREAT WORK ON AGRICULTURE.

D. APPLETON & CO., 413 and 445 BROADWAY, N. Y.,
HAVE JUST PUBLISHED

The Natural Laws of Husbandry,

BY
JUSTUS VON LIEBIG,

EDITED BY
JOHN BLYTH, M. D.,

Professor of Chemistry in Queen's College, Cork.

1 vol., 12mo. Cloth. 387 pages, \$1 50.

- Chap. I. The Plant.
- Chap. II. The Soil.
- Chap. III. Action of Soil on Food of Plants in Manure.
- Chap. IV. Farm Yard Manure.
- Chap. V. The System of Farm Yard Manuring.
- Chap. VI. Guano.
- Chap. VII. Fertilizers—Human Excrements.
- Chap. VIII. Earthy Phosphates.
- Chap. IX. Ground Rape-Cake.
- Chap. X. Wood-Ash.
- Chap. XI. Ammonia and Nitric Acid.
- Chap. XII. Common Salt, Nitrate of Soda, Salts of Ammonia, Gypsum, Lime.

The work is especially adapted to the promotion of Agriculture, and should be read by all intelligent farmers throughout the country.—*Rochester Democrat & American.*

This volume should be studied by all cultivators of the soil, as treating of their business in the fullest and most enlightened manner; and to the men of science it presents much that is of general interest.—*Boston Traveller.*

Sent to any address in the United States, free of postage, on receipt of price.

Randall's Youatt on the Horse,

A complete treatise on the

Structure, Diseases, and Management of the Horse.

Edited by Hon. H. S. RANDALL, LL.D., Author of "The Practical Shepherd," "Sheep Husbandry," &c., &c.

This popular work so well adapted to the wants of the American People, by one of their most practical and successful Stock Growers, should be in the hands of every breeder, and owner of Horses.

RANDALL'S YOUATT

comprises 483 large duodecimo pages, well illustrated by 60 anatomical cuts, and other engravings, making the BEST AND MOST PRACTICAL WORK on the subject published.

Send for circular of the "GEM OF CANVASSING BOOKS." Agents wanted for every section of the country. Address E. F. HOVEY, General Agent, No. 13 Spruce-street, New-York.

Now Ready.

THE KEY-NOTE;

A new collection of Sacred and Secular Music, for Singing Schools, Choirs, Congregations, and social use.

BY WM. B. BRADBURY,
AUTHOR OF THE "JUBILEE," AND MANY OTHER MUSICAL WORKS.

ONE HUNDRED pages are devoted to the Elements of Music, with a great amount of new Singing School Music, and nearly THREE HUNDRED pages to Sacred Music, as Tunes of all metres, Anthems, Chants, and other Set Pieces, mostly new. The work is printed throughout from large plain type, one part on a staff.

The immense success of Mr. Bradbury's previous works, and their almost unexampled sale (of his last work in this department, THE JUBILEE, more than two hundred thousand copies have already been sold), prove his knowledge of the wants of the public, and his ability to supply them.

The present work was designed for publication last year, but having been delayed because of the unfavorable times, the author has had opportunity to perfect it in its various departments. As a SINGING SCHOOL BOOK, THE KEY-NOTE is still more comprehensive and complete, than its predecessors, while to Choirs, Congregations, Societies, &c., it presents the results of Mr. Bradbury's labors in composing and collecting for several years. Price, \$10 per dozen. All our publications are for sale in Boston by MASON & HAMLIN, 274 Washington-st., at our prices.

MASON BROTHERS, Publishers,
5 & 7 Mercer-st., New-York.

LIGHTHILL'S BOOK ON DEAFNESS.

A New Edition Now Ready

OF

THE POPULAR TREATISE

ON

DEAFNESS;

Its Causes and Prevention.

BY

DR. E. B. LIGHTHILL.

One Small 12mo., with Illustrations. Price \$1.

—o—

The very remarkable sale of this little volume

is a sufficient guaranty of its popularity and value. Three

editions have been sold within as many months, and a fourth

is just ready.

—o—

The author's aim has been to produce a book

FOR THE PEOPLE,

not for the medical profession, but for afflicted individuals

and families, who, wishing information upon the subject,

have heretofore been at a loss for any work treating in un-

professional language upon Deafness and its attending

evils. This book fills such a vacuum. It is clear and com-

prehensive.

—o—

The New-York Observer says: "There is a large amount

of useful information here embodied for the million, to

teach them how to guard against deafness, and how to treat

it when coming on."

—o—

The Boston Commercial Bulletin says: "An excellent and

comprehensive little treatise, written in a clear and com-

mon-sense style, easily understood."

—o—

"The suggestions in relation to the every-day treatment

of the ear are of the most valuable kind, and should be

within the reach of every family." [Buffalo, Courier,

—o—

The work should find its way into the hands of every in-

dividual suffering with deafness, or any accompanying

affliction. Its value will be at once appreciated.

—o—

. Sold by Booksellers everywhere, and it will be sent by

mail free on receipt of \$1, by

CARLETON, Publisher,

(late RUDD & CARLETON.)

No. 413 Broadway, corner Lispenard-st., N. Y.

The Independent.

This weekly Religious, Literary, and Family Journal,
edited by

Rev. Henry Ward Beecher,

Rev. Joshua Leavitt, D.D.,

And Theodore Tilton,

Is issued in the same form and at the same low price of

TWO DOLLARS

Per Annum, notwithstanding the great advance in white paper.

It affords its Readers :

Fair and thoughtful editorial discussions of the most important facts, occurrences, and interests of this Nation, and of the World.

A comprehensive record of facts, men, and movements of the Religious World.

A full and careful weekly history of the progress of the Rebellion.

Ample chronicles of the important general news, home and Foreign.

Fair and careful accounts of new books; made on the express principle of serving as a safe guide to buyers.

Interesting correspondence from Washington, from the West, from the Army, from Abroad.

Six columns a week of carefully selected matter for Family Reading; being prose and poetry, suited to interest both the Old and Young.

A full chronicle of the progress of business, and of the Current Prices of merchandise, produce, and live stock in New-York City.

A carefully prepared

COMMERCIAL & FINANCIAL ARTICLE,

embracing the latest and most reliable information in regard to the money market, trade, commerce, and business generally. In this department The Independent has secured a valuable reputation for fairness, boldness, and for discussing all secular topics from the highest moral stand-point.

A DRY GOODS REPORT,

furnished particularly for country merchants, a weekly report of the prices current in this city of all descriptions of Domestic dry goods. The information thus furnished, so ENTIRELY RELIABLE, cannot be found in any other periodical. We have the best of evidence on that point from all quarters. We are not permitted to give the names of the parties who make this weekly report to us, but will state that they are two competent merchants, with entirely different connections, and that they are well known throughout the United States, and have been for years. The prices given are the exact figures at which the several descriptions of goods are sold for NET CASH by the jobbing houses in this city ON THE DAY SAID REPORT IS MADE, viz.: Wednesday of each week.

ONE SERMON EVERY WEEK,

BY

Rev. Henry Ward Beecher.

THE FOLLOWING EMINENT WRITERS ARE

SPECIAL CONTRIBUTORS TO ITS COLUMNS:

WILLIAM ALLEN BUTLER,

REV. THEODORE L. CUYLER,

REV. ROBERT M. HATFIELD,

HORACE GREELEY

BAYARD TAYLOR,

JOHN G. WHITTIER.

TERMS.—\$2 per annum, paid in advance. Specimen numbers sent gratis.

JOSEPH H. RICHARDS, Publisher,

No. 5 Beekman Street, New York.

FOR SALE BY NEWS AGENTS.

PROSPECTUS FOR 1864.

THE NEW YORK OBSERVER

IS A RELIGIOUS AND SECULAR

NEWSPAPER,

PUBLISHED ON A DOUBLE SHEET, SO AS TO BE

EASILY SEPARATED INTO

TWO DISTINCT PAPERS.

In Religion it is free from sectarianism, and gives a full, fair and impartial report every week of all matters of general interest

IN ALL THE DENOMINATIONS.

In Politics it is entirely free from party relations or affinities, discussing great principles with freedom and candor, and giving the fullest and latest intelligence of all the movements of the day.

IT SUPPORTS THE GOVERNMENT

WITH VIGOR, FIDELITY AND ZEAL,

in its efforts to

CRUSH THE REBELLION

and restore the Union and preserve the Constitution. It criticises with freedom whatever measures are not adapted to the accomplishment of these ends; but its steady purpose, from the beginning of the war, has been, and will be, to uphold the hands and strengthen the heart of the Government, while it puts forth its energies to protect us against the most unbloody rebellion that ever disturbed the peace of any country.

The N. Y. Observer is the most complete family newspaper IN THE WORLD.

In the variety of its Departments,

In the fulness of its Information,

In the extent of its Correspondence,

In the number of minds enlisted in its Editorial and other columns,

In the amount of money expended in procuring materials to enrich and adorn its pages,

In the healthful, religious, conservative, genial tone that pervades the paper,

In its stores of anecdote, biography, poetry, science, art, and general literature, it will strive to exceed every other weekly newspaper.

For each NEW SUBSCRIBER under FIVE in number, 50 cents.

For FIVE OR MORE NEW SUBSCRIBERS, sent at one time, we will give \$1 for each.

Specimen copies of the paper sent free to any address.

TERMS.

\$2.50 in advance; \$3.00 after 3 months; \$3.50 after 6 months.

Address SIDNEY E. MORSE, JR., & CO.,

37 Park Row, New-York.

(Established in 1841.)

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,

(For either the English or German Edition.)

One copy, one year.....	\$1 00
Six copies, one year.....	5 00
Ten or more copies one year.....	80 cents each.

Add to the above rates: Postage to Canada, 12 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only three cents a quarter, if paid in advance at the office where it is received.

Address all communications to the Editor and Proprietor, ORANGE JUDD, 41 Park-Row, New-York City.

A Few Special Words to All our Readers, and Particularly to those whose Term of Subscription expires with this Number.

I. The usual Circular Notice of Expiration will not be sent out this year. We are retrenching all outside expenses for circulars, show-bills, etc., in order to be able to increase the intrinsic value of the journal itself, and yet keep to the old terms. Many have renewed already, and those whose time expires at other seasons of the year will doubtless remember the fact.

II. We have confidence that all our present readers will deem it a pleasure to continue to receive the *Agriculturist*. We can well promise that the next volume will be far more valuable than any previous one. Our working force is now larger than ever before. At least five thoroughly competent, earnest, practical men, will devote their whole time and energy to collecting and condensing into these pages the greatest possible amount of really useful, reliable information. Each one of these men is abundantly able to issue a good paper alone, and some of them have done so. But it saves time and expense to the reader, to thus have all the labor and energies of so many men concentrated upon one Journal. The greater subscription list, and the larger working force, give greater facilities for more careful investigation of facts, principles, and modes of practice. Single items of but a few lines often contain the result of several hours of examination, sometimes requiring many miles of travel. (For example, the single article on Willow Feuces, on page 362, required a journey of between 2000 and 3000 miles, involving much time and expense.) The *Agriculturist* must and shall be a constant treasury of knowledge, a reliable source of good information upon all matters pertaining to the FARM and its adjuncts, to the GARDEN, and to the HOUSEHOLD—not omitting the rising generation. Well executed ENGRAVINGS, of a pleasing and instructive character, those which convey more information than words could do, will continue to be a prominent feature. We have the facilities for carrying out these plans, and shall do so. We do not intend to be excelled nor equalled, either in the amount of practical, useful, reliable information given, or in the low price at which it is afforded to the public.

III. We therefore respectfully and cordially invite every one whose time now expires, to renew for another year; and we further solicit the kind words of all our readers in making this journal known to those who are as yet unacquainted with it. A word from a reader is far more effective with strangers, than anything the publisher can say. There are over three million Farmers in our country, not more than one in twenty of whom read any journal devoted to their own important calling. There are at least a million Mechanics, Merchants and Professional men, many of them having garden plots, and all of them households, who would doubtless be benefited by the hints and suggestions given from month to month in the *Agriculturist*. We believe we are not entirely selfish in desiring to place this journal in as many of these families as possible. Will the reader not take pleasure in aiding in this work? Let us reach at least a full hundred thousand of the four million families referred to—about one in forty! The multitude are not aware of the advantage of receiving the hints and suggestions derived from the experience of others, until they have tried it. It is a good work to induce them to take and read a journal devoted to their calling, and designed to promote their interests. On another page we have offered some remuneration to those devoting time to collecting larger clubs. We will earnestly labor to do our part in making the paper worthy of a place in every family in the land. Will the reader aid the enterprise by returning the form below, or a similar one, with his own, and one, two, three, or more other names—or with other names, if his own is already forwarded for 1864? We look for the response with confidence.

IV. Printing paper now costs about double the price of two years ago, and all other expenses are much greater; but thanks to the kind aid of our readers in enlarging the list of subscribers, we have gone through the year without the loss we looked for when, twelve months ago, we decided not to follow the general course of “raising prices.” Printing paper has recently gone up at least one third, but having secured a considerable supply ahead, we hope to be able to go through another year with no increase in the price to subscribers. It can be done if our readers continue their liberal efforts to keep up and increase the list. In reality we are furnishing the paper at about half the former price, taking into account the rise in materials and labor, the heavy government tax paid on printing paper, on advertisements, license, etc.

V. We ask, as a SPECIAL FAVOR, to have renewals and new names sent in at once, that our experienced clerks may have all the month to get the names properly entered and arranged upon the mail books—a work of no small magnitude, where, as in this office, every name is recorded, and written on the wrappers. This will save a world of hurry toward the close of the month, and the employment of clerks inexperienced in this department. Please favor us in this respect.

VI. Recording names in the form below, will save writing a formal letter. Seal the letter well, and direct simply to Orange Judd, New-York City. See hints on sending money, p. 356.

SUBSCRIBERS TO THE AMERICAN AGRICULTURIST, BEGINNING WITH VOLUME 23—JANUARY 1st, 1864.

(Terms—in Advance: \$1 a year.... Six Subscribers, \$5.... Ten or more, \$0 cents each. An extra copy for 15 names—if no premiums are taken.)
